OPERATION DEEP FREEZE 60

1959-1960

OCEANOGRAPHIC SURVEY RESULTS

Oceanographic Branch
Marine Surveys Division

JUNE 1961

U. S. NAVY HYDROGRAPHIC OFFICE
WASHINGTON 25, D. C.
Price $1.75

ABSTRACT

Results of oceanographic research during the U.S. Navy operations in support of DEEP FREEZE 60, 1959—1960, are presented. Observations in areas of the Antarctic, Antarctic Convergence, and South Pacific were made from aboard four icebreakers, USS BURTON ISLAND (AGB-1), USS ATKA (AGB-3), USS GLACIER (AGB-4), and USCGC EASTWIND (WAGB -279). Ships' tracks to, in, and from the Antarctic and locations of all oceanographic stations are given.

In Eastern Balleny Basin, surface temperatures ranged from —0.44° to —1.58°C. Within the surface layer, temperature decreased to a depth of about 100 meters and then increased to a maximum of greater than 1.25°C, indicating the upper level of the Antarctic Circumpolar Water. Surface salinities were low (less than 34.00%), reflecting Antarctic summer conditions. Values increased rapidly to 34.50% in the upper 200 meters with salinity maxima occurring between 600 and 1,200 meters depth.

A west-east line of stations taken in McMurdo Sound is discussed. An extremely low temperature structure was noted, with temperatures from surface to bottom not exceeding 0.00°C throughout the water column. The effects of ice in the area were evident by low surface temperatures and salinities. Below the surface layer, temperatures decreased gradually to values as low as —1.93°C near the bottom of the deeper stations.

Near the Ross Ice Shelf, several stations were taken along a northwest to southeast track to the shelf and the other, along a track closely paralleling the shelf edge. Throughout the areas temperatures were less than 0°C, the degree of coldness indicating distance from the Ice Shelf. Surface values ranged from —0.40°C at about 60 miles from the Shelf, to —1.42°C at its edge. Salinities varied little, increasing slightly from surface to bottom (maximum differences not exceeding 00.35%).

Oceanographic observations were made for the first time in the Bellingshausen Sea off the Eights Coast. Observed surface temperatures were low (from —1.50° to —1.75°C) and showed no indication of summer warming. Below the 150-meter depth, temperatures increased rapidly to 1.00°C at 450 meters. Salinities increased with depth from a surface minimum of 32.95% to values greater than 34.50% below 350 meters.

Several transits across the Antarctic Convergence were made and the results from surface and subsurface measurements dilineate the positions of the Convergence, as well as the water dissimilarities.

Ice observations and reconnaissance by the ships are discussed and presented.

Fourty-eight bottom samples were collected and analyzed. These are discussed by area, and detail results of the analyses are presented in Appendix B.

FOREWORD

DEEP FREEZE 60 was the sixth consecutive United States expedition in support of Antarctic research. Personnel from the U. S. Navy Hydrographic Office, supported by the National Science Foundation, conducted marine geophysical research from several icebreakers of TASK FORCE 43. In addition to oceanographic studies in the Ross Sea, Amundsen-Bellingshausen Seas, and South Pacific Ocean, stations were occupied along the Thurston Peninsula during the first successful penetration into the previously unexplored Bellingshausen Sea. The analyses and tabulation of data collected are presented in this report.

I. INTRODUCTION

A. Purpose

Operation DEEP FREEZE 60 (1959-1960) was a continuation of United States support of scientific effort in the Antarctic. It also marked the sixth consecutive year of U. S. Navy Hydrographic Office participation in obtaining oceanographic-hydrographic data in Antarctic waters. The Hydrographic Office's work during DEEP FREEZE 60 was supported by the National Science Foundation. During DEEP FREEZE 60 considerably more ship time was provided for oceanographic work than in previous years.

Surveys were conducted in the Ross and Amundsen-Bellingshausen Seas, McMurdo Sound, the area of the Antarctic Convergence, Bransfield Strait at Palmer Peninsula, and across the Drake Passage. In addition, one of the vessels conducted surveys along the west coast of South America during transit to and from the Antarctic.

B. Summary of Operations

Oceanographic-hydrographic data were obtained from aboard four icebreakers, USS GLACIER (AGB-4), USS BURTON ISLAND (AGB-1), USS ATKA (AGB-3), and USCGC EASTWIND (WAGB-279). Observations were made on a not-to-interfere basis with the vessels primary mission. Three icebreakers carried oceanographers and bathythermograph (BT) teams, while the fourth had aboard a bathythermograph team only.

Tracks made by the ships conducting survey operations are shown by Figure 1. The shaded portion of this figure indicates an area of numerous track lines by several vessels. The locations of stations made by the icebreakers in the Ross Sea, McMurdo Sound, South American Quadrant, and Thurston Peninsula are presented in Figures 2 through 5, respectively. Basic observations, in each of these areas consisted of vertical temperature measurements, collection of water, bottom, and biological samples. Also, limited gravity measurements were made. While underway, between stations and in transit from one area to another, continuous temperature recordings, soundings, ice and meteorological observations, BT lowerings, and surface water collections were made. Table 1 summarizes these observations by ship.

C. Methods

Vertical temperature measurements were made by standard Nansen casts employing paired reversing thermometers. The corrected observed values were averaged when differences did not exceed 0.06°C. Depth of observation was determined by thermometric calculation from protected and unprotected thermometers.

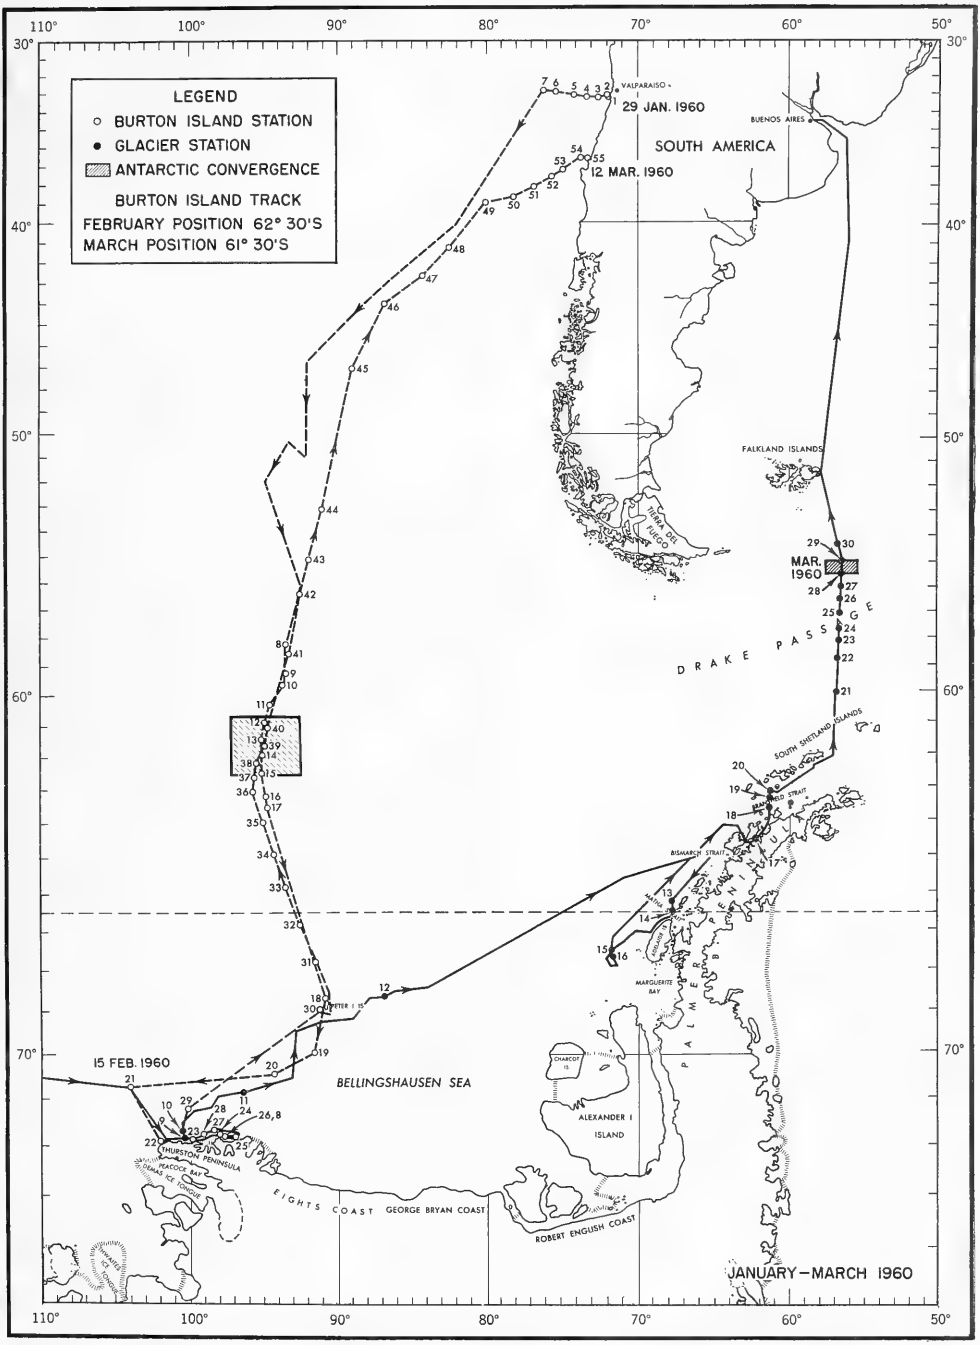

FIGURE 4. OCEANOGRAPHIC STATION LOCATIONS, SOUTH AMERICAN QUADRANT

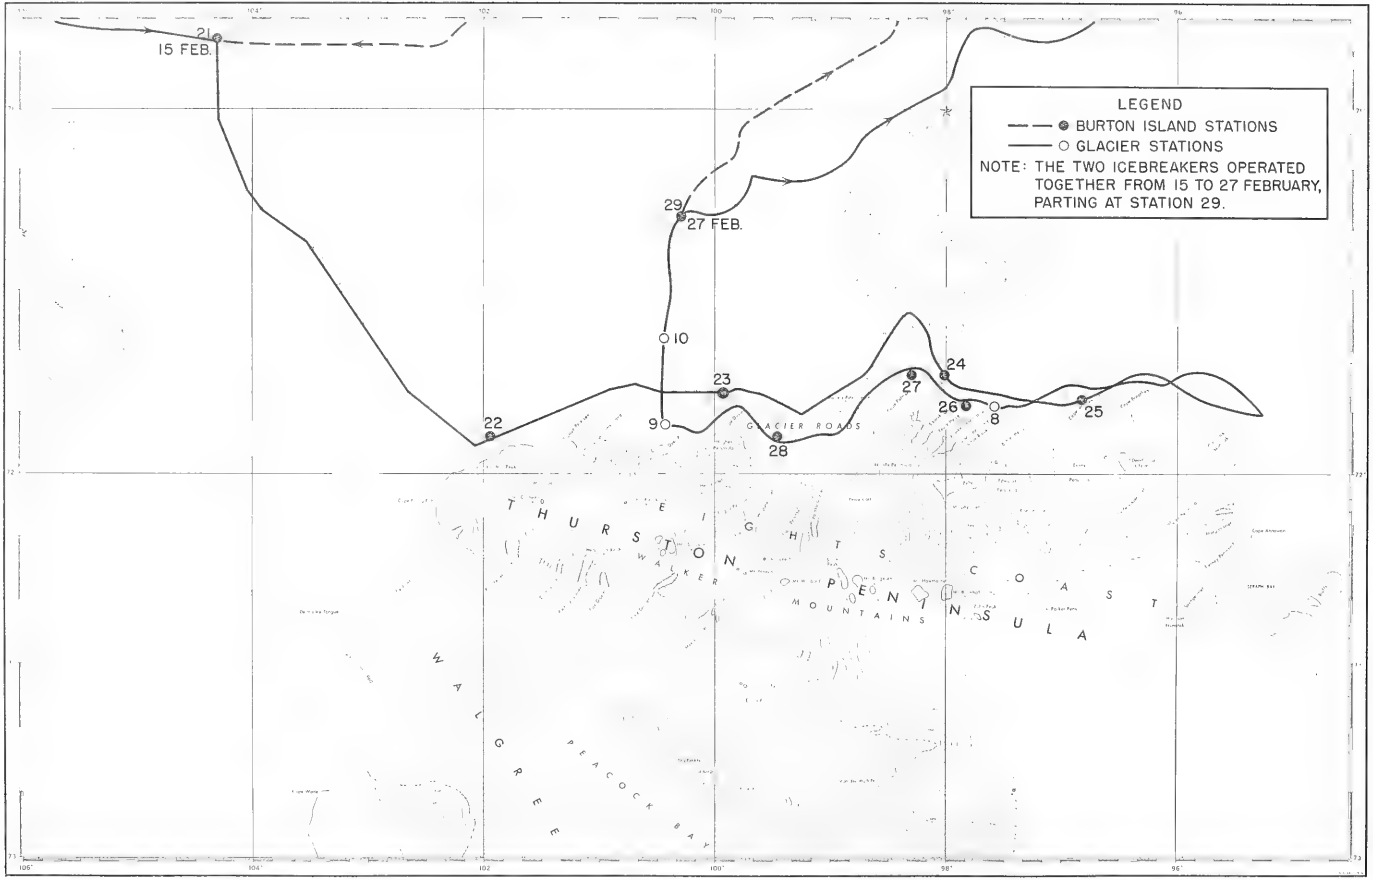

FIGURE 5. OCEANOGRAPHIC STATION LOCATIONS IN THE THURSTON PENINSULA AREA, FEBRUARY 1960

Salinity samples obtained from Nansen bottles were stored in gasket-sealed, 360-ml glass citrate bottles for return to the Hydrographic Office. Analysis was made by a University of Washington conductivity bridge. Duplicate runs were made on each sample; accuracies are considered good to within 0.01 parts per thousand (‰).

Dissolved oxygen samples were analyzed aboard ship by a modified Winkler method. Duplicate analyses were made on all samples; where variations greater than 0.05 ml/l occurred between two readings, a third titration was made.

The foregoing observed data were evaluated and coded for processing by a Burrough's DATATRON computer. Machine computations provide temperature, salinity, and oxygen interpolation at standard depths, and calculations of density, anomaly of dynamic depth, and sound velocity. Listings of these data are given in APPENDIX A.

TABLE 1. SUMMARY OF OCEANOGRAPHIC OBSERVATIONS - DEEP FREEZE 60

	BURTON ISLAND	GLACIER	ATKA	EASTWIND
Ocean Stations	55	30	18	20
Oxygen Stations	41	12	-	6
BT's	731	586	1,757	789
Miles of Soundings	6,900	18,920	22,360	24,856
Miles of Ice Track	690	4,760	4,225	500
Miles of Continuous Temperature Records	6,190	2,120	-	9,000
Sea and Swell Obs.	417	392	431	534
Water Samples for Other Agencies	22	6	-	27
Surface Water Samples	14	183	-	394
Plankton Tows	6	4	-	-
Dredge Hauls	1	-	-	-
Bottom Grab Samples	1	2	-	-
Core Samples	8	18	-	19
Gravity Measurements	-	22	-	11
Rock Collections	-	4	-	1

Additional observations by other ships: ARNEB - 202 BT's,
PETERSON - 623 BT's

BT lowerings with 900-foot instrument were scheduled on an hourly basis aboard the four icebreakers and on a 4-hour basis on other ships of the Task Force. A total of 4,688 BT lowerings was made, including observations taken during transit to and from the Antarctic. Prints of these slides and the accompanying weather observations are on file with the

U. S. Navy Hydrographic Office. BT transects across the Antarctic Convergence Zone are presented in this report as cross sections.

Bottom samples were collected by Phleger corers, a Kullenberg-type corer with a 4-inch-diameter plastic barrel, and an Orange-peel grab sampler. All samples thus obtained were returned to this Office for laboratory analyses. Forty-eight samples were taken in the Ross Sea, McMurdo Sound, Amundsen and Bellingshausen Seas, and the Palmer Peninsula area. Results of these analyses are listed in APPENDIX B. Numerous rock samples were obtained from various islands and other locations in the Antarctic.

Ice observations were made aboard all icebreakers by the BT team at hourly intervals and the aerographers at 3-hour intervals. These observations include ice concentration, thickness, age, and type, and are presented graphically for different areas and periods. In addition, the ships' quartermasters made regular ice observations and entered concentrations in the ships' logs.

Meteorological and sea and swell observations were made from 1- to 3-hour intervals by aerographers assigned to each icebreaker. These data were recorded on standard WBAN forms and forwarded to the National Weather Record Center, Asheville, North Carolina. Surface weather observations also were taken during each Nansen cast (APPENDIX A) and BT lowering.

Continuous underway soundings by UQN-1B echo sounders were made by all ships. In addition, a detailed sounding program was accomplished around Scott and Peter I Islands. A sounding track was made to the west of Coulman Island in the Ross Sea and along the Thurston Peninsula in the Amundsen and Bellingshausen Seas, where no soundings previously had been made. Echograms and sounding journals were forwarded to the Hydrographic Office for incorporation into new and revised nautical charts.

Continuous air/sea temperature measurements were made with resistance bulb thermometers and recorded by a 4-channel Brown recorder. The sea element was trailed just below the water surface, and the air element was installed above the main deck level. Measurements were made by the EASTWIND in the Antarctic and Pacific between Panama, Australia, and Tasmanian Sea; BURTON ISLAND, along the western coast of South America into the Bellingshausen Sea and return to United States; and GLACIER, from New Zealand to the ice in the Amundsen Sea, and from the Bellingshausen Sea north along the east coast of South America to the Sargasso Sea. A portion across the Antarctic Convergence in the Drake Passage is included in this report. All records are on file in the U. S. Navy Hydrographic Office.

Surface water samples were collected in route to and from the Antarctic and areas of open water in the Antarctic. Most of these were 360-ml samples for salinity determinations. Some were collected in $\frac{1}{2}$-gallon quantities for the National Institute of Oceanography, Wormley, England, and Institute of Meteorology, Stockholm, Sweden.

Additional observations taken during DEEP FREEZE 60 included gravity measurements by a Lacoste-Romberg geodetic gravimeter; biological samplings, plankton nets and dredge; transparency, black and white Secchi discs; and water color by a modified Forel scale covering the blue-green-yellow color range.

D. Participating Personnel

The following four oceanographers from the U. S. Navy Hydrographic Office participated aboard icebreakers on Operation DEEP FREEZE 60:

Robert B. Starr	USS GLACIER
James Q. Tierney	USS BURTON ISLAND
Richard H. Evans	USS BURTON ISLAND
Lloyd W. Wilson	USCGC EASTWIND

q In addition, LCDR J. Morgan (USN), TASK FORCE 43, supervised all ocean stations taken by ATKA, and the GLACIER stations along the Ross Ice Shelf.

E. Other DEEP FREEZE Publications

Since 1954, the U. S. Navy Hydrographic Office has been conducting oceanographic survey operations in the Antarctic in support of the DEEP FREEZE program. The oceanographic results are presented in the following reports:

REPORT NO.	SHORT TITLE	HYDRO REF. NO.	SHIP(S)
HO 16331	Pre-DEEP FREEZE (1954-1955)	00504	USS ATKA

*Final report in preparation; however, data listings are available.

II. ROSS SEA - MCMURDO SOUND AREA, OCEANOGRAPHY

A. General

The Ross Sea lies south of the Pacific Ocean between 160°E and 150°W. It is a large open body of water with depths generally less than 400 fathoms and with free circulation to the circumpolar ocean waters to the north. To the south, the sea is bounded by the floating seaward margin of the Ross Ice Shelf. Many glaciers and small ice shelves extend along its margins, but in spite of this, a relatively large percentage of land is exposed during the summer season.

McMurdo Sound is located in the southwestern part of the Ross Sea, bounded on the west by the Victoria Range of Antarctica, on the east by Ross Island, and on the south-southeast by the Ross Ice Shelf. The United States Antarctic station, Naval Air Facility McMurdo, is located on the western coast of Cape Armitage at Hut Point, the southernmost point on Ross Island.

Kainan Bay is a small bay in the Ross Ice Shelf, in the eastern Ross Sea, approximately 400 miles east of Ross Island. Little America V Station (no longer in operation) is located on the Ross Ice Shelf, two to three miles inland of Kainan Bay.

Sea ice forms in the Ross Sea during the autumn and winter seasons, but usually breaks up sufficiently in late summer to permit ship transit to all corners of the sea. A general east to west set removes much of the ice and bergs, but some are confined in a gyral in the northern portions.

Three icebreakers operated in the Ross Sea at various times from December 1959 into March 1960. During these months, a total of 45 oceanographic stations was taken. Figure 2 shows by different symbols the tracks and stations occupied by these ships. In addition, the locations of the Antarctic Convergence Zone, as indicated by ATKA BT's are illustrated.

Serial-depth temperature and salinity observations were made on all oceanographic stations. Determinations for dissolved oxygen were made at only five stations across the eastern Balleny Basin. Data for the eastern Balleny Basin and for McMurdo Sound are presented in Figures 6 and 7, respectively. No profiles were prepared for the western Ross Sea and the Ross Ice Shelf areas.

B. Physical Properties

1. Eastern Balleny Basin (Figures 2 and 6)

Five oceanographic stations were taken across the Balleny Basin along 179°E longitude from 13 through 16 January 1960. Data were obtained from surface to bottom. Stations 2 and 3 were made in the basin with

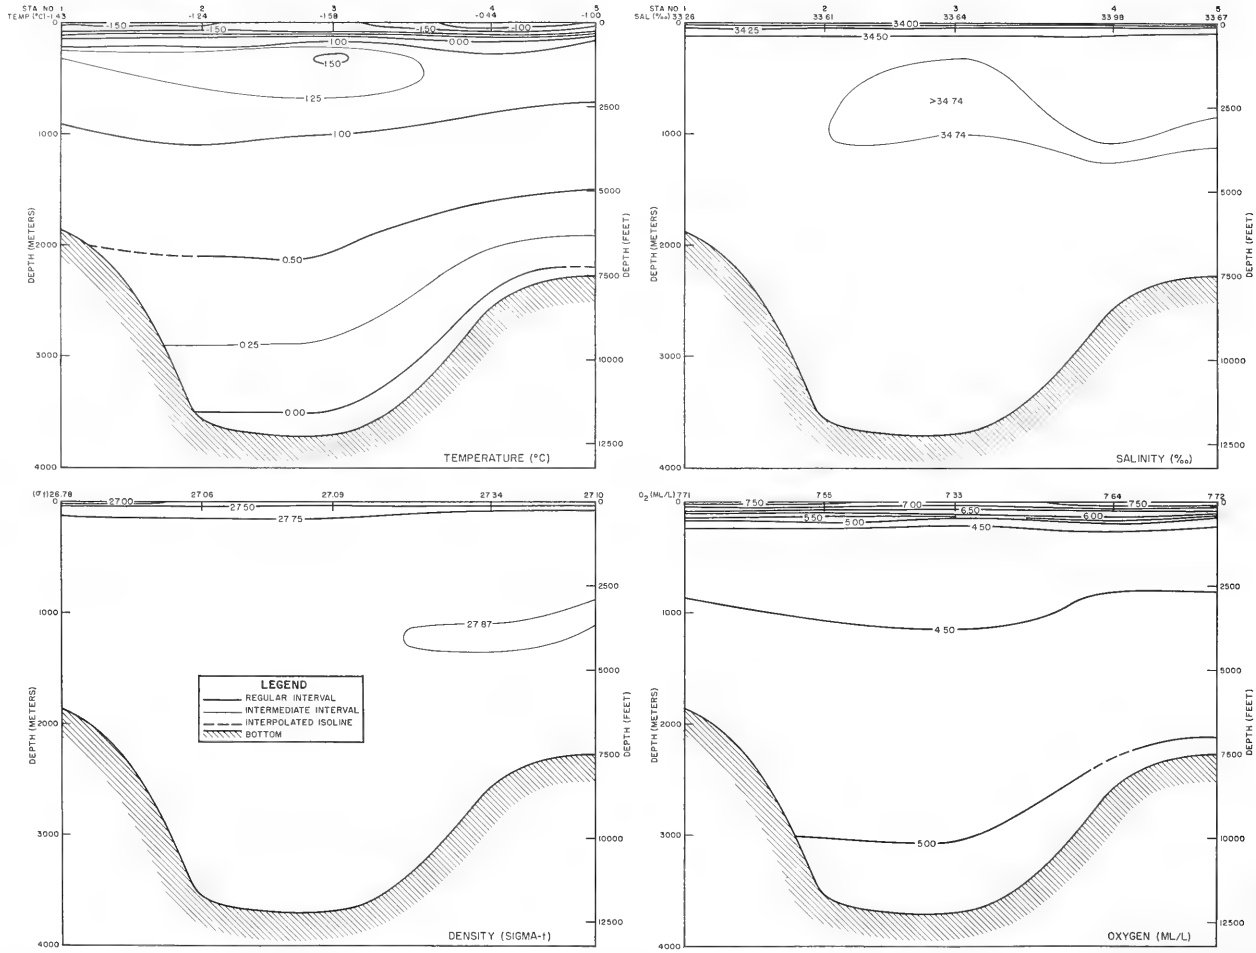

FIGURE 6. VERTICAL DISTRIBUTION OF TEMPERATURE, SALINITY, DENSITY, OXYGEN – EASTERN BALLENY BASIN, 11-13 JANUARY 1960, USCGC EASTWIND

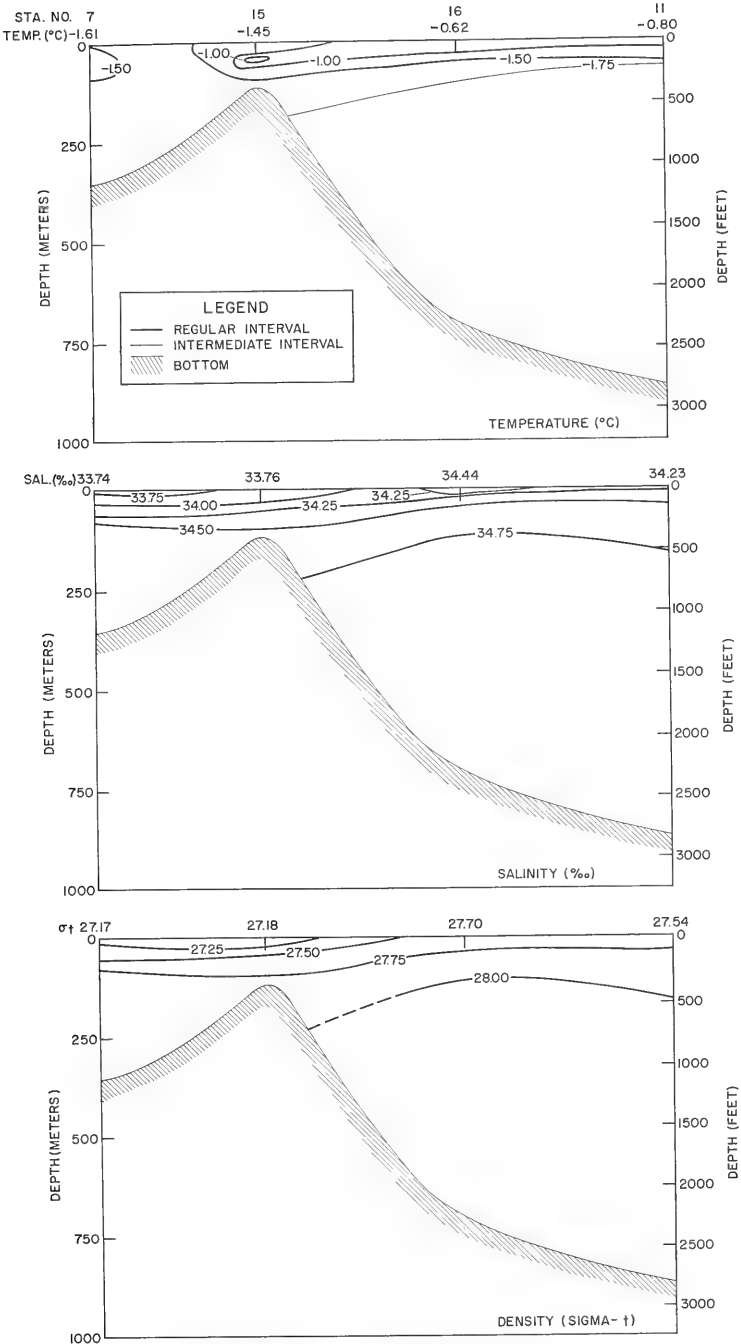

FIGURE 7. VERTICAL DISTRIBUTION OF TEMPERATURE, SALINITY, AND DENSITY IN McMURDO SOUND, 31 JANUARY–1 FEBRUARY 1960

depths greater than 3,000 meters; stations 1, 4, and 5 were made on the ridges with depths less than 2,600 meters.

a. Temperature

Surface temperatures for the five stations ranged from -0.44° to -1.58°C. Within the surface layer, temperature decreased to -1.50°C at a depth of about 100 meters, except at station 3, where temperatures increased slightly from -1.58° to -1.50°C at 100 meters. Below 100 meters, temperature increased in the transition zone to a maximum of greater than 1.25°C, indicating the upper level of the Antarctic Circumpolar Water. On station 3, the deepest station in the basin, temperatures exceeded 1.50°C between 280 and 360 meters depth. Temperature maxima on stations 4 and 5 were less than 1.25°C. From 500 to 600 meters to the bottom, temperatures decreased gradually with depth through the Circumpolar Water. Although the bottom temperature on station 3 was less than 0°C, salinities around 34.70 ‰ preclude presence of Antarctic Bottom Water.

b. Salinity

Surface salinities were less than 34.00 ‰, reflecting Antarctic summer conditions. Within the surface layer, values increased rapidly to 34.50 ‰ in the upper 200 meters. Just below this, values of 34.70 ‰ were observed, delineating Circumpolar Water. Salinity maxima occurred between 600 and 1,200 meters depth. Below this, values decreased only 0.02 to 0.04 ‰ to the bottom, where about 34.71 ‰ was observed on all stations.

c. Density

Values at the surface ranged from a low of 26.78 at the northernmost station to a high of 27.34 at station 4 to the south. Immediately below the surface, densities increased rapidly with the 27.75 isopycnal between 100 and 150 meters. Below this, densities gradually increased to 27.86 near the bottom on station 1, and 27.88 and 27.89 at stations 2 through 5. A cell of water with a density of 27.87 and greater was observed at mid-depth on stations 4 and 5, coinciding with the high salinity values obtained.

d. Oxygen

From a surface high of greater than 7.00 ml/l, oxygen content decreased rapidly in the surface layer, reaching a minimum of less than 4.50 ml/l at approximately 500 meters. From this level to the bottom, oxygen content increased only slightly with depth.

2. McMurdo Sound (Figures 3 and 7)

Fifteen oceanographic stations were occupied in and around McMurdo Sound aboard EASTWIND from 26 January through 13 February 1960. Figure 3

shows the locations and sequence of 14 of these stations. Station 18 lies off the chart north of Cape Bird. Stations 7, 15, 16, and 11, taken 31 January to 1 February, were selected to represent a west-east transect across McMurdo Sound. Of these, stations 7 and 15 were taken when ice was present, whereas 16 and 11 were taken in open water. Figure 7 presents the vertical distribution of temperature, salinity, and density for these stations.

a. Temperature

The extremely low temperature structure in McMurdo Sound is readily seen in Figure 7. Throughout the water column, all values were less than 0.00°C. Summer warming of the surface layer is evident at stations 11 and 16, where slight negative gradients were formed. The local effects of melting ice at stations 7 and 15 resulted in the very low surface temperatures and resultant positive gradients. Below this, temperatures decreased gradually to values as low as -1.93°C near the bottom at the deeper stations.

b. Salinity

The low surface salinities occurring at stations 7 and 15 are due to melting ice; values at stations 11 and 16 are normal for the open areas.

c. Density

The density pattern parallels that of salinity; values were slightly lower in areas of ice and higher in the more open waters. Low temperatures and high salinities account for the high density values of greater than 28.00 near the bottom at the deeper stations.

3. Western Ross Sea

From 1 to 6 January, ATKA conducted a series of oceanographic stations to the west of Scott Island in an area bounded by 65° to 69°S and 175°E to 180° (Fig. 2). Because of the vertical sampling interval, no cross sections have been prepared. The tabulated data, however, are presented in APPENDIX A. These data show a similar physical structure to the stations taken across the Balleny Basin by EASTWIND (Fig. 6).

4. Ross Ice Shelf

Six oceanographic stations were taken in the vicinity of the Ross Ice Shelf by GLACIER from 13 to 17 December 1959. Three of these were taken along a northwest to southeast track to the shelf and the other three closely paralleling the shelf edge (Fig. 2). Throughout the area, temperatures were less than 0°C. Surface values ranged from -0.40°C, at

about 60 miles from the shelf, to -1.42°C at the ice shelf. Temperatures decreased from the surface to minimum values at the maximum depth sampled; a minimum of -1.94°C was observed at 550 meters on station 7. On several stations, there was evidence of slightly warmer water occurring at various depths in the water column.

Surface salinities varied little from stations 2 through 7. The seemingly high values (34.45 to 34.51 ‰) are most likely a result of the early sampling period. From the surface to the bottom, salinities increased slightly with maximum differences not exceeding 00.35 ‰. On some stations, there are indications of a very slight salinity minimum immediately below the surface layer. On approaching the ice shelf, the deeper isohalines appear to dip sharply as indicated by a salinity of 34.58 ‰, which occurs at 250 meters on station 2 and 500 meters on station 4. A maximum value of 34.84 ‰ was observed close to the bottom at station 7.

III. BELLINGSHAUSEN SEA, OCEANOGRAPHY

A. General

Previous to DEEP FREEZE 60, no oceanographic stations are known to have been taken in the sector of the Bellingshausen Sea off the Eights Coast. Ice conditions permitted penetration into this area by GLACIER and BURTON ISLAND in February 1960. Oceanographic stations were occupied along the coast of Thurston Peninsula and northward to Peter I Island. The locations of these and the ships' tracks are shown in Figures 4 and 5.

The configuration of the continent along the Palmer Peninsula, and to some extent bottom contours, produce eddies and countercurrents which force water from the East Wind Drift across the Antarctic Divergence into the West Wind Drift forming a clockwise gyral in the Bellingshausen Sea.

B. Physical Properties

The vertical distribution of physical properties is shown by Figures 8 and 9. Figure 8 is a cross section of nine stations extending from Cape Flying Fish eastward, closely paralleling the coast to about 97°W. Depths at the stations varied widely, 165 to 1,000 meters. Figure 9 is a cross section of three stations taken from a point about two miles from the coast to about thirty miles to the north. These varied from 300 to 550 meters in depth.

1. Temperature

Surface temperatures were low at all stations; values ranged from a high of -1.50°C to a low of -1.75°C, showing no trend or indication of summer warming. In general, temperatures increased from the surface to the -1.50°C isotherm at about 150 meters except where it appears at 50 meters on station 23. Below this, values increased more rapidly, with the 1.00°C isotherm being observed at 450 meters, near the maximum depth sampled. At the easternmost stations, an intrusion of colder water at mid-depth was noted from the data. Cells of slightly warmer water also were observed at several stations.

2. Salinity

Salinities increased with depth from a surface minimum of 32.95 ‰ at the northernmost station (Fig. 9) to values of greater than 34.50 ‰ below 350 meters. The greatest increase was in the surface layer, the 34.00 ‰ isohaline being observed at 100 meters or less. This isohaline reached 35 meters on station B129 and approximately 50 meters at B123. Lower salinities at mid-depth on the four easternmost stations also indicated the presence of an intrusion of a different water type.

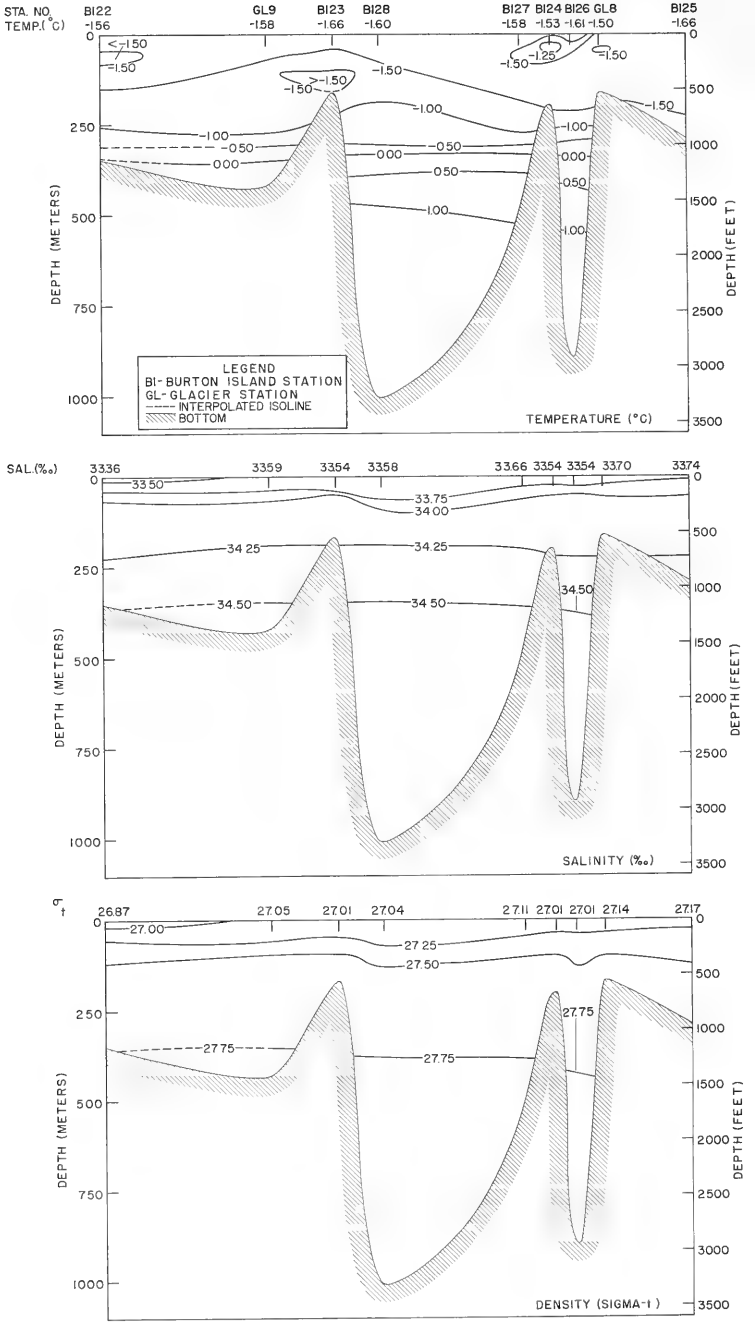

FIGURE 8. VERTICAL DISTRIBUTION OF TEMPERATURE, SALINITY, AND DENSITY IN THE BELLINGSHAUSEN SEA, USS GLACIER AND USS BURTON ISLAND, 16–25 FEBRUARY 1960

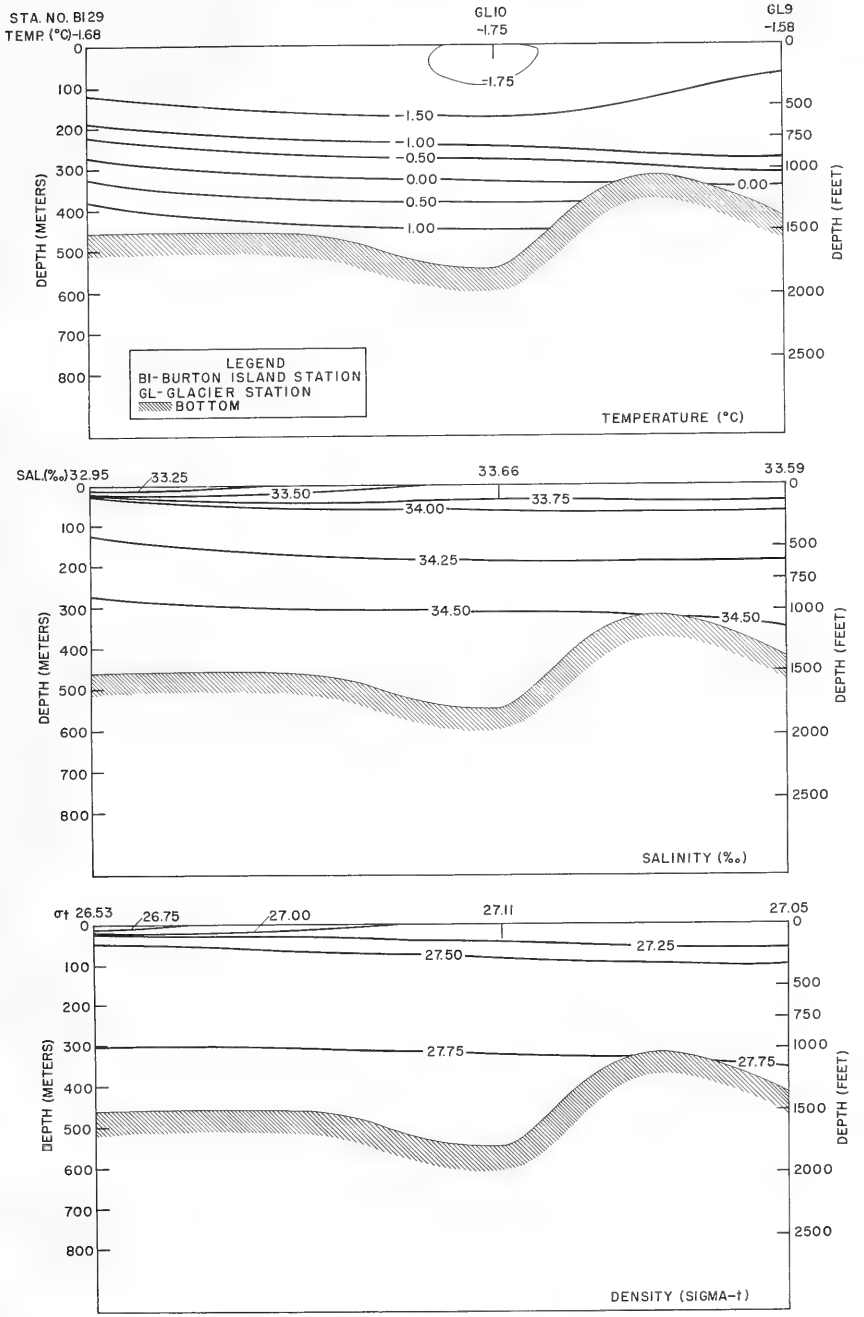

FIGURE 9. VERTICAL DISTRIBUTION OF TEMPERATURE, SALINITY, AND DENSITY IN THE BELLINGSHAUSEN SEA, USS GLACIER AND USS BURTON ISLAND, 24-27 FEBRUARY 1960

3. Density

The density structure closely follows the salinity pattern, with the lowest surface value being noted at station B129. Near the surface, densities increased rapidly to an isopycnal of 27.50, occurring at approximately 100 meters or less. Values increased to 27.75 at 350 meters depth.

IV. BRANSFIELD STRAIT - DRAKE PASSAGE, OCEANOGRAPHY

A. General

Bransfield Strait is a comparatively narrow passage between the northern tip of Palmer Peninsula and the South Shetland Islands. Its width, between Trinity Island to the south and Deception Island to the north, is approximately 60 miles. This strait is almost always ice free during the greater part of the Antarctic summer.

To the north of the South Shetland Islands lies Drake Passage, which separates Antarctica from South America by a distance of about 450 miles. Water circulation through the passage is from west to east induced by the West Wind Drift. The water passing through this passage is considerably warmer than that flowing through Bransfield Strait. The Antarctic Convergence, as observed on this survey, was located between 55°15'S and 55°30'S.

B. Physical Properties

Three oceanographic stations (18, 19, and 20) were occupied across Bransfield Strait aboard GLACIER on 10 March 1960 (Fig. 4). Soundings for these stations were 622, 1,189 and 494 meters, respectively. Figure 10 presents vertical distribution of temperature, salinity, density, and oxygen. The physical properties in the upper 100 meters of this cross section correspond closely with continental shelf water of low temperature and salinity values and high oxygen content. Below this level to maximum sampling depths, a transition toward Bottom Water appears with evidence of possibly a southern boundary of Circumpolar Water near station 20.

Ten stations were occupied by GLACIER across Drake Passage during the period 12 and 13 March along the 057°W meridian from 60°S to approximately 54°S. Sonic depths for stations 21 through 28 were around 4,000 meters with the depth shoaling to 82 meters on station 30. Figure 11 presents vertical distribution of temperature, salinity, and density.

Figure 4 shows ships' tracks and station locations for both of these areas.

1. Bransfield Strait (Figure 10)

a. Temperature

Surface temperatures ranged from 0.50 to 0.75°C, with the minimum temperature noted at station 19. A slight negative gradient, resulting from surface seasonal warming, occurred to about 100 meters where minimum temperatures were observed. Below this, values increased slightly with depth to the maximum depths sampled.

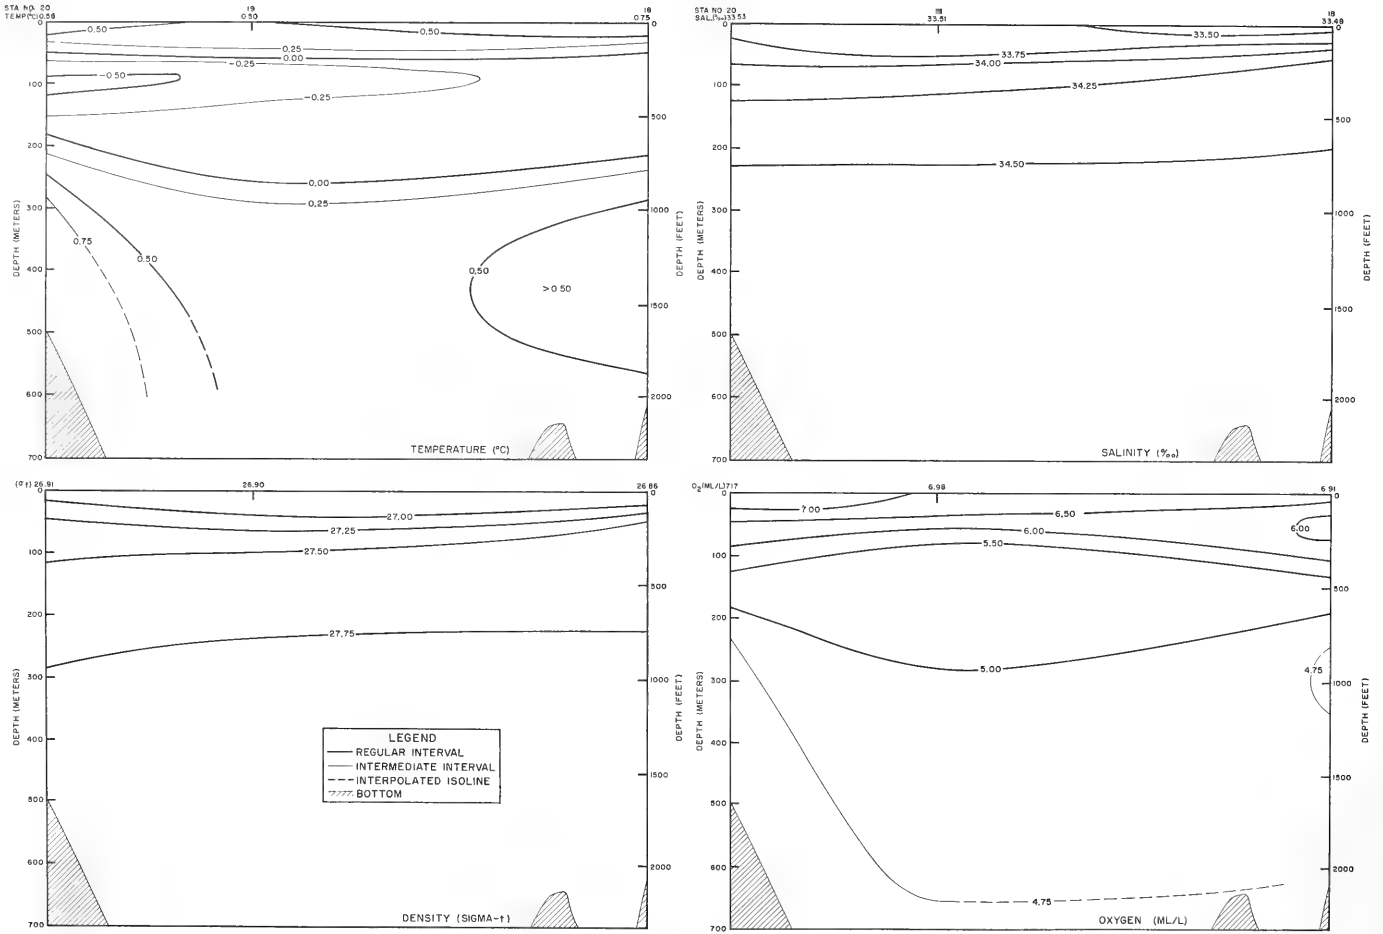

FIGURE 10. VERTICAL DISTRIBUTION OF TEMPERATURE, SALINITY, DENSITY, AND OXYGEN ACROSS BRANSFIELD STRAIT, USS GLACIER, 10 MARCH 1960

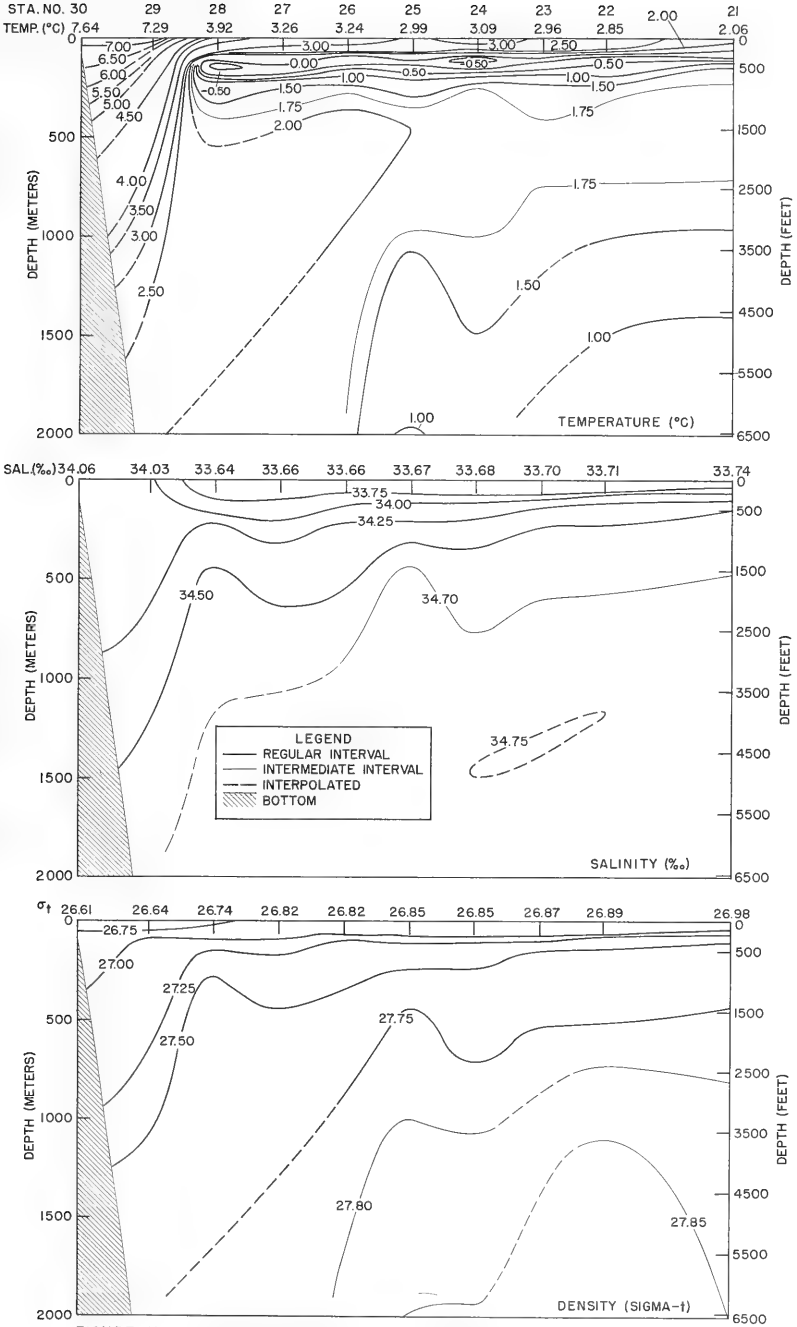

FIGURE 11. VERTICAL DISTRIBUTION OF TEMPERATURE, SALINITY, AND DENSITY ACROSS DRAKE PASSAGE, USS GLACIER, 12-13 MARCH 1960

b. Salinity

Salinity distribution was uniform across Bransfield Strait and varied only slightly, approximately 1.00 ‰ vertically to the depths sampled. From low surface values caused by summer ice melt to a depth of about 150 meters, maximum salinity changes occurred. Below this depth, salinities changed little, about 0.05 ‰, to the lowest depth sampled.

c. Density

The configuration of the isopycnals closely followed the isohalines, both horizontally and with depth. Densities increased from 26.90 at the surface to as high as 27.85 at the deepest observation.

d. Oxygen

A high surface value of dissolved oxygen, 7.17 ml/l, was observed at station 20. Below the surface, values varied from about 7.00 to 4.75 ml/l at maximum sampling depths on stations 18 and 19. At station 20, the 4.75 ml/l oxygen isoline was at 230 meters and dipped to 660 meters at station 19. Station 18 shows cells of lower oxygen at approximately 75 and 300 meters depth.

2. Drake Passage (Figure 11)

a. Temperature

This is an excellent cross section of temperature from Antarctic into Subantarctic regions crossing the Antarctic Convergence. The Convergence is readily apparent between stations 28 and 29, where surface values increased more than 3°C within a very short distance (approximately 15 nm). In this zone, the cold water from the Antarctic surface layer sinks beneath the considerably warmer and less dense waters from the north to form the well-defined Antarctic Intermediate Water Mass.

The rise of deep, warm water from the north is shown by the 2° isotherm. This water continues southward, forming the Antarctic Circumpolar Water, between 400 and 700 meters, with maximum temperatures at about 500 meters. Below the Circumpolar Water, temperatures gradually decreased with depth in a transition zone. The very cold and deep Antarctic Bottom Water was not reached.

b. Salinity

From the southernmost station northward, the layer of Antarctic Surface Water, with salinities less than 34.00 ‰, increased in depth from 50 to 200 meters just south of the Convergence. In the

vicinity of the Convergence, these low salinities shoaled to the surface. Below this, the 34.25 and 34.50 ‰ isohalines parallel the 34.00 ‰ to the Convergence where they turn sharply downward to the north, indicating the Antarctic Intermediate Water. The characteristic salinity minimum at the core of Intermediate Water is not evident, possibly owing to the sampling interval.

Below the surface layer, the 34.70 ‰ isohaline is indicative of Antarctic Circumpolar Water. Below the Circumpolar Water, a salinity maximum of greater than 34.75 ‰ was noted in the transition zone at about 1,300 meters, stations 22 through 24. Salinity decreased only 0.05‰ from here to the greatest depth shown on the cross section.

c. Density

In the Antarctic Surface Water, isopycnals closely parallel the salinity pattern, with densities increasing from less than 27.00 to approximately 27.50. North of the Convergence, these isopycnals dip sharply. On the two stations north of the Convergence, a 26.75 isopycnal lies just below the surface, delineating Subantarctic Surface Water from Antarctic Surface Water. The 27.75 isopycnal parallels the 34.70 ‰ isohaline where the warm, deep water rises to form the Circumpolar Water. Densities greater than 27.85 were observed in the transition water on the southernmost stations.

V. ANTARCTIC CONVERGENCE

A. General

The Antarctic Convergence is considered as the zone where the cold and more dense surface water of the Antarctic region sinks below the warmer and less dense surface water to the north. This zone is usually marked by a sharp north-south decrease in the surface water temperature of 1° to 3°C (2° to 6°F). The mean surface temperature associated with this drop is about 2°C (36°F) during January through March; this gradient (north to south temperature decrease) is also generally found at moderate depths. The mean temperature of the Convergence surface gradient decreases as winter approaches. At greater depths, sinking water mixes with adjacent water and eventually spreads to the north as the Antarctic Intermediate Water, recognizable by its minimum salinity. It is emphasized that the main water circulation in the Convergence area is west to east, and the north-south movements are vectors of small magnitude.

Four temperature profiles are presented from data collected by a 900-foot BT across the Convergence. BT's were taken half-hourly except when prevented by rough seas. One other Convergence crossing is presented with temperature, salinity, and density profiles. These data were obtained by Nansen casts.

B. Bathythermograph Sections

1. Figure 12 presents the vertical distribution of temperatures for two crossings of the Antarctic Convergence taken by ATKA south of New Zealand, towards McMurdo Sound. The first is the result of observations made in January 1960. The position, during this early summer crossing, was between 62°30'S. and 63°S. This section provides a good example of the major characteristics of the Convergence. The rapid surface temperature change, 37° to 33°F in about fifteen miles, and the nearly vertical isotherms in this zone are clearly indicated. To the north, the Subantarctic Water is shown with an isothermal layer to about 300 feet; to the south, the Antarctic Surface Water, with an isothermal layer to about 150 feet.

The second crossing by ATKA was made during March 1960, between 61°47'S and 62°30'S. The Convergence in this section is not so readily apparent by a rapid surface change; however, below the surface, the typical structure is noted. During this period, late summer, the surface layer of the Antarctic Surface Water is considerably deeper.

2. Figure 13 is a crossing of the Convergence made by GLACIER during transit from New Zealand to Thurston Peninsula in February 1960. The vessel crossed the Convergence at an angle, at approximately 60° to 61°S. An interesting feature of this section is the warmer surface layer of the Antarctic Surface Water than noted in the previous cross sections of this report.

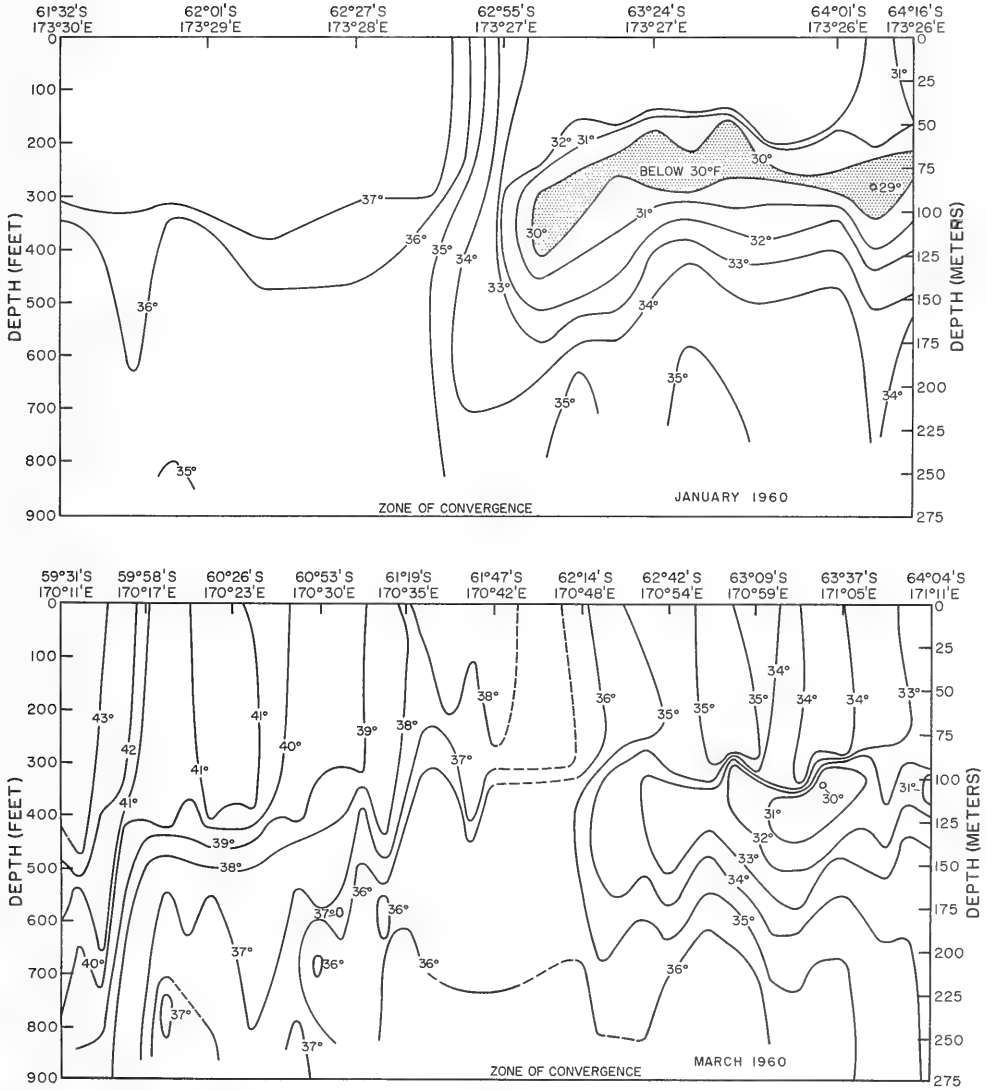

FIGURE 12. VERTICAL DISTRIBUTION OF TEMPERATURE (°F), PACIFIC ANTARCTIC CONVERGENCE, USS ATKA

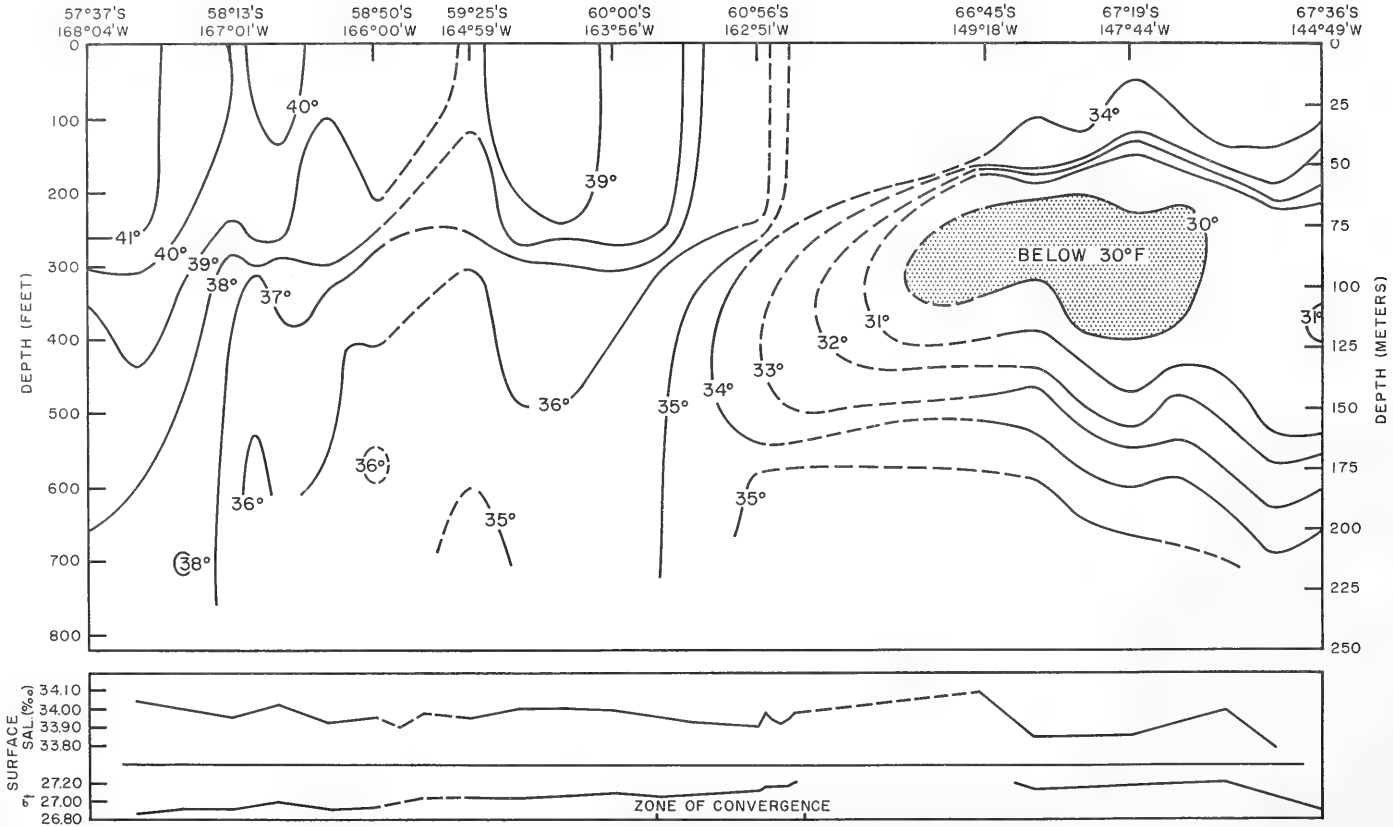

FIGURE 13. VERTICAL DISTRIBUTION OF TEMPERATURE (°F), PACIFIC ANTARCTIC CONVERGENCE, USS GLACIER, FEBRUARY 1960

3. BURTON ISLAND crossed the Convergence during March 1960 from about 61° to 65°S along the 91° through 95°W meridians. During this crossing, both BT and Nansen cast observations were made.

Figure 14 presents the results of BT observations, showing detailed surface structure.

It is noted that the Convergence Zone in this section compared to previous sections appears to be considerably broader. South of the Convergence, surface temperatures decrease regularly, with water of temperatures less than 30°F appearing at the surface at the southern end of this section.

C. Oceanographic Station Sections

During February, BURTON ISLAND occupied stations southward from Valparaiso, Chile, to the vicinity of Thurston Peninsula. In March, the ship returned along approximately the same track, taking a continuous series of stations from Peter I Island to Concepcion, Chile. Oceanographic conditions observed to the 2000-meter depth during this leg are shown in Figures 15 and 16. The cross section for temperature indicates the Convergence near stations 39 (60°41'S) and 40 (61°11'S). Observational depths in this vicinity were limited to about 500 meters, owing to adverse sea conditions.

These sections are good examples of physical conditions characteristic of the Antarctic and Subantarctic regions. The main features of the water masses are discussed in previous sections; however, these figures show physical features much farther north than the others.

A series of oceanographic stations was made across the Convergence in Drake Passage by GLACIER during March 1960. Figure 4 shows the position of the Convergence in this area and Figure 11 presents vertical distribution of the physical properties of the water. A discussion of this crossing is in Section IV, Drake Passage Oceanography.

D. Continuous Surface Temperature Record

Figure 17 is a continuous trace of surface water and shade-air temperatures, measured by resistance bulb thermometers, across the Antarctic Convergence in Drake Passage. Temperatures increased from 3.4° at 55°22.4'S to 7.2°C at 55°14'S. Associated air temperatures gradually increased from 5.8° to 7.3°C.

VI. ICE CONDITIONS

A. General

Ice conditions in the Antarctic were recorded aboard ATKA, EASTWIND, GLACIER, and BURTON ISLAND, annotating percent concentration, thickness, age, topography, and snow cover. These data are portrayed by conventional ice symbols along ships' tracks. Widths of tracks illustrated vary according to visibility conditions at time of observation. Figures 18 through 22 illustrate ice conditions in the Western Ross Sea from December through March; Figure 23, for the Amundsen and Bellingshausen Seas during February; and Figure 24, along the western coast of the Palmer Peninsula during March.

B. Geographic Area

1. Ross Sea Area

Aboard GLACIER on 9 December 1959, the first icebergs and growlers were sighted at 60°30'S, 177°E (Fig. 18). The pack, varying from five- to eight-tenths concentration of average thickness four to five feet, was entered shortly thereafter. At about 74°S, the ship entered open water on 12 December and remained in this until reaching Kainan Bay. GLACIER and ARNEB departed Kainan Bay on 18 December for McMurdo Sound, transiting open water to the vicinity of Beaufort Island. Grounded icebergs blocked passage of the ships between Beaufort Island and Cape Bird. GLACIER left McMurdo 9 January for New Zealand, passing through intermittent patches of one and five-tenths concentration to about 65°S; no ice was sighted north of this.

ATKA also entered the ice pack on 9 December 1959, reporting three- and four-tenths coverage of young and slush ice at approximately 65°30'S (Fig. 19). The concentration increased to seven-tenths of winter ice at 70°S. Thickness of this ice varied from three to five feet with large floes and fields predominating. From 70°S to the vicinity of Franklin Island, the ship operated in open water, except for a patch of nine-tenths winter and young ice at 72°S. McMurdo Sound was filled with eight-tenths concentration of five-foot bay ice from 13 through 15 December. This ice extended north midway between Beaufort Island and Franklin Island.

On 1 January 1960, ATKA sailed northward to conduct oceanographic stations in the vicinity of Scott Island. After passing through five- and eight-tenths ice in McMurdo Sound (Fig. 20), open water was reached at about 76°S, near Franklin Island. Ice was again encountered at 71°S, 177°E, where three- and four-tenths of block and brash were reported. From 71° to 66°S, and in the vicinity of Scott Island, concentrations varied from four- to seven-tenths of block, brash, and slush with an average thickness of three feet, during the period 3 through 5

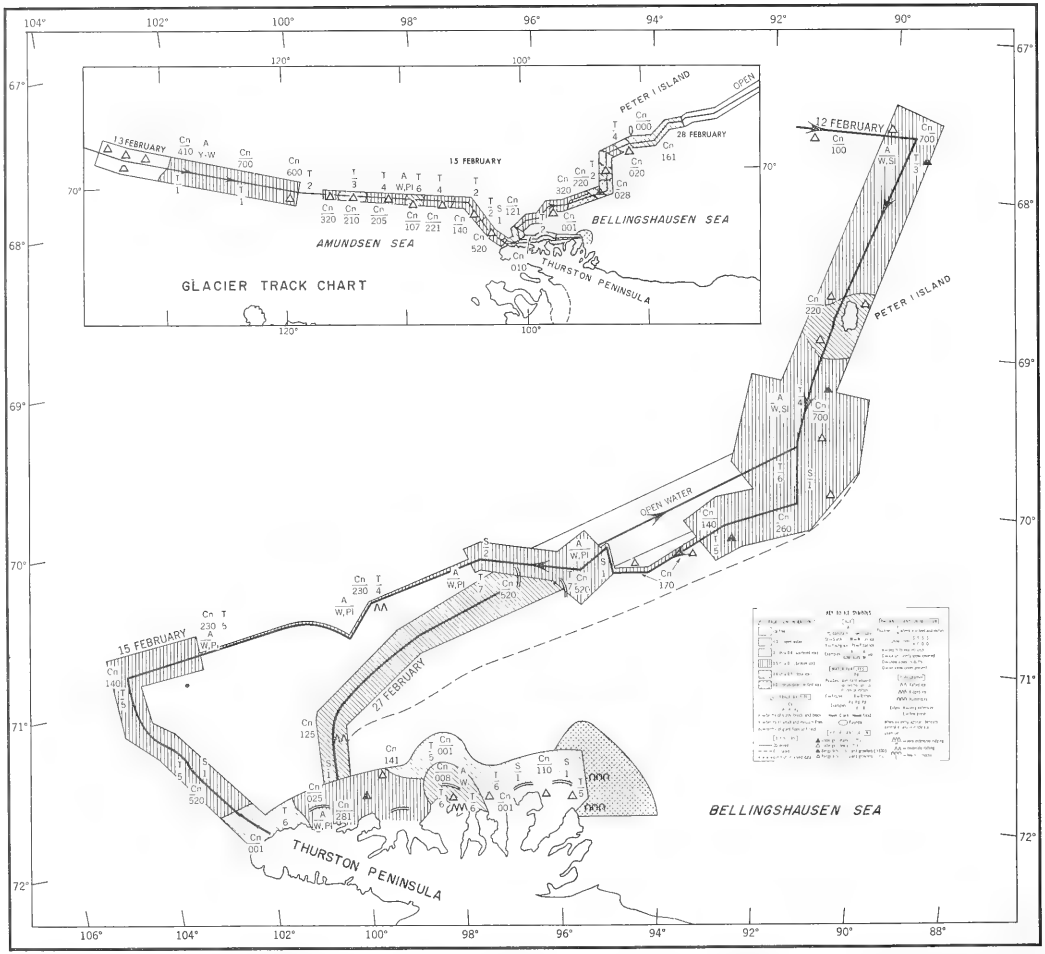

FIGURE 23. ICE CONDITIONS, AMUNDSEN-BELLINGSHAUSEN SEAS, USS BURTON ISLAND AND USS GLACIER, FEBRUARY 1960

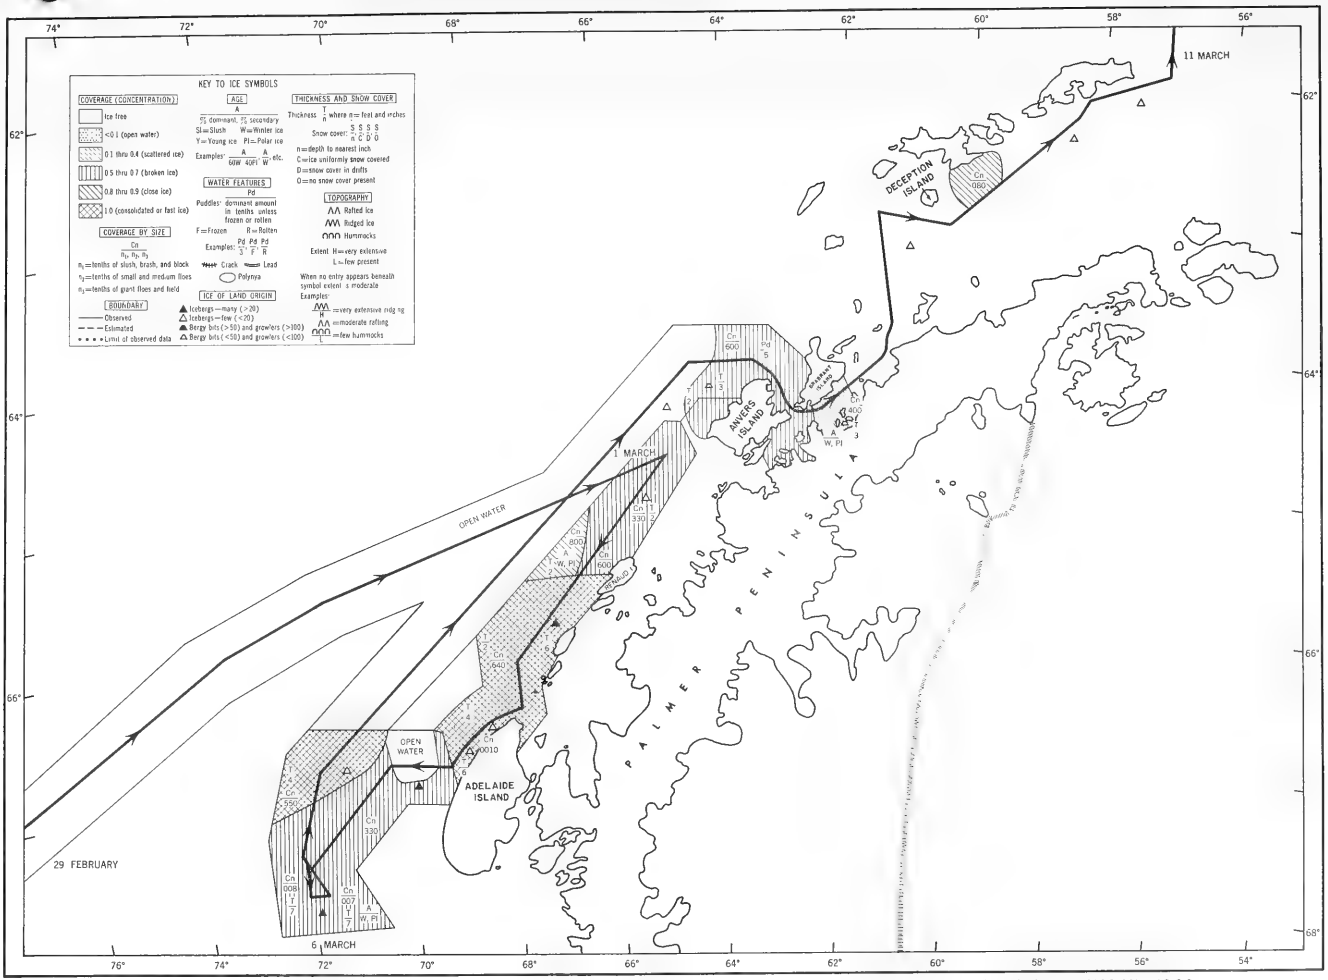

FIGURE 24. ICE CONDITIONS, PALMER PENINSULA AREA, USS GLACIER, MARCH 1960.

January. On the return trip, open water was traversed south of 70°30'S to McMurdo, where ice was re-entered.

From 12 through 15 March 1960, ATKA proceeded to McMurdo Sound and then north via Hallett Station, west of the 173°E meridian (Fig. 21). Ice was encountered all along the ship's track to Cape Adare, except around Coulman Island. New ice was rapidly forming. From McMurdo to Coulman Island, this new ice was young slush, varying from three- to eight tenths concentration and averaging one-foot thick. In contrast to this, along the coast from Cape Hallett to Cape Adare, the ice was primarily rotten winter ice, two- and three-foot thick block and brash, with young ice secondary. Six- to eight-tenths concentration was recorded. After departing the ice north of Cape Adare, no ice was encountered.

EASTWIND first entered ice at approximately 68°S, 179°E, on 13 January 1960, while in transit from New Zealand to McMurdo Sound (Fig. 22). From this position to 73°30'S, the concentration varied from one- to nine-tenths of brash, block, and small and medium floes of two- to four-foot thickness. No ice was observed from 73°30'S to the vicinity of Beaufort Island, where nine-tenths coverage was encountered.

In McMurdo Sound, small, medium, and large floes of five-foot thickness were concentrated along the western shore and to the north of Marble Point. Fast bay ice extended as far north as Tent Island.

On 2 February, the ship departed McMurdo for Hallett Station. Little ice was encountered before arriving in the vicinity of Moubray Bay, where five- to seven-tenths concentration was entered. Hallett Harbor was ice free except for a few grounded bergs on 3 February. During three days at Hallett, up to five-tenths concentration of ice moved in and out of the harbor daily with the changes of tide. On 6 February, EASTWIND departed Hallett Station for McMurdo escorting ARNEB. Their route was to the west of Coulman Island through five- to seven-tenths of brash, block, and small floes, averaging four-foot thick. Open water extended from just south of Coulman Island to McMurdo Sound.

EASTWIND departed McMurdo 27 February for Sidney, Australia, via Hallett Station. At the time of departure, the fast bay ice extended about two miles north of NAF McMurdo, from the Glacier Tongue to the Dailey Islands. After leaving McMurdo Sound area, the only ice encountered was in the vicinity of Cape Hallett where the same ice conditions existed as reported above.

2. Amundsen - Bellingshausen Seas Area

While proceeding southward to rendezvous with GLACIER for scientific survey operations at the Thurston Peninsula area, BURTON ISLAND first sighted ice on 12 February at 67°30'S, 92°W (Fig. 23).

Several large icebergs and light brash of one-tenth coverage were observed. Shortly thereafter, three-foot ice of seven-tenths concentration was entered; these conditions prevailed to the vicinity of Peter I Island. Four-tenths coverage of brash, block, and small floes with scattered bergs surrounded the island. From just south of the island to about 70°30'S, 94°W, ice conditions worsened, changing from predominantly brash and block to a high concentration of small and medium floes. These floes contained ice of seven-foot thickness. From here and proceeding westward to the rendezvous point, ice conditions improved. Although concentrations ranged from five- to seven-tenths, there was a marked reduction in percentage of small and medium floes.

GLACIER first observed ice at 69°43'S, 130°16'W, on 13 February (Inset, Fig. 23). In contrast to the ice encountered by BURTON ISLAND in the Bellingshausen Sea, the ice observed by GLACIER in the Amundsen Sea was thin and rotten, presenting little difficulty to the ship's movement. A few bergs were noticed along the track. Concentrations varied up to eight-tenths.

The two ships rendezvoused 15 February and proceeded southward to the Thurston Peninsula, passing through ice of five- to eight-tenths concentration, about five-foot thick, with a snow cover in excess of one foot. Upon arrival 15 February, the ships followed a shore lead, about three miles wide, eastward along the coast. Ice along the lead was predominantly one- to two-tenths with intermittent patches of five- to eight-tenths coverage. Very thick fast ice prevented further eastward passage. This ice was several years old and very heavily hummocked. The concentration was nine-tenths to total coverage, and individual floes were sometimes several miles across and over ten-foot thick. Helicopter reconnaissance revealed a shore lead to the southeast off Eights Coast; however, the ice pack to the north appeared to be virtually impassable.

After conducting survey operations in the Thurston Peninsula area, the ships proceeded northward from the vicinity of Williams Island about 25 February. Progress was slowed by soft ice of nine-tenths coverage and temporarily stopped by ice under pressure. On 26 and 27 February, the ships headed in an easterly direction, making little progress owing to heavy concentrations of pressure-ridged ice and poor visibility. On 27 February, GLACIER and BURTON ISLAND parted company at about 71°S, 100°W, in relatively open water and proceeded toward Peter I Island, maintaining distances of five and ten miles from the edge of the ice pack, respectively. GLACIER encountered intermittent patches of ice to the vicinity of Peter I Island, while enroute to Palmer Peninsula. BURTON ISLAND passed through mostly open water and reported the last observed ice at 69°S.

3. Palmer Peninsula Area

On 1 March, GLACIER again entered ice off Anvers Island along the

western coast of Palmer Peninsula (Fig. 24). The ship sailed southward along the coast, passing through two-foot thick ice of concentrations of six- to ten-tenths to the vicinity of Renaud Island. South of this to Adelaide Island, ice under pressure reduced ship's movement to a minimum. West of Adelaide, ice conditions improved as six-tenths concentration was reported on 5 March. At this time, GLACIER met the Chilean ice-breaker, ARA GENERAL SAN MARTIN, and escorted her to open water. GLACIER turned southward, following leads through ice of six- to eight-tenths coverage and reached the Danish vessel, MV KISTA DAN, at 68°S,71°W, on 6 March. By 8 March, pressure on the ice field diminished sufficiently, and the pack opened enough for GLACIER to escort the vessel to open water. GLACIER then proceeded to Deception Island. Open water prevailed except in the passage between Anvers and Brabant Islands and DeGerlache Strait, where six- and four-tenths of brash and block were encountered, respectively. The last ice observed consisted of a few icebergs and shore-fast ice as far north as King George Island.

VII. BOTTOM SEDIMENTS

A. General

The distribution of bottom sediments appears to be related in a general way to distance from the Antarctic Continent and depth of water. The sediments sampled in depths less than 500 fathoms are principally of terrigenous origin and may be classified as a marine glacial till with two important exceptions: (1) the volcanic ash deposits of McMurdo Sound and in the vicinity of Ross Island, Peter I Island, and other volcanic features, and (2) the predominantly biological sediments with an irregular and undertermined distribution. Varying amounts of organic constituents are associated with the terrigenous sediments; the most frequent being siliceous sponge spicules. The features common to all of these sediments are the lack of chemical weathering and their poor sorting. Ice rafting is presumably the most effective transporting agent.

In water deeper than 500 fathoms, the few botton sediments collected are composed generally of sufficient planktonic micro-organisms to be classed as organic deposits, except where local conditions prevail. These local variations are found in the vicinity of islands and at the base of the Antarctic Contentinental Slope. Part of these sediments appear to be the result of ice rafting, as well as other transporting agents.

Identifications and percentages of organic and inorganic constituents are only gross approximations of the major elements comprising the sand and larger fractions. In particular, any volcanic derivative is grouped under volcanic glass, and pyroxene includes all ferromagnesium minerals such as augite and horneblende. Also, the percentages given for planktonic micro-organisms, particularly at the top of cores and in grab samples, are probably low since some of these constituents, especially diatoms, are evidently lost during sampling and laboratory processing. However, micro-scopic examination of the silts and comparison with the coarser fractions of about one-third of the samples agreed reasonably well in the diatom estimates. Perhaps the delicate forms do not occur in appreciable percentages in many of the sediments since the only diatoms seen in the sand fractions were two large, thick walled species of Coscinodiscus.

B. Areal Description

1. Ross Sea Area

a. McMurdo Sound - The terrigenous sediments sampled in the Ross Sea are divisible into two provinces depending on their source. Those derived from Ross Island and associated volcanics are one of these. Fifteen cores of predominantly volcanic glass and feldspar were obtained by EASTWIND in McMurdo Sound. In some few cases, rock fragments or organic remains comprise the primary components.

The sediment types range mostly from olive gray to greenish black silts and sands. Their mineral grains, for the most part, average medium to medium high in sphericity; subangular to subrounded in roundness; and dull-pitted to polished-pitted in surface texture. Although the bottom of McMurdo Sound appears to be very irregular, hard, and variable in composition there seems to be a general decrease of mean phi size and biological content with increasing water depth. Charting distribution of the biological constituents indicates there is possibly an increase in the planktonic micro-organism content of the sediments from west to east and from south to north.

b. Southwestern Ross Sea - EASTWIND cores 14 and 15 were obtained in slightly over 400 fathoms of water, one to the north and the other to the south of Beaufort Island. Although only about 20 miles apart, they differ materially in composition. The northern core (14) consists primarily of the remains of planktonic organisms throughout its entire length, excluding the very bottom where volcanic glass and feldspar become the predominant constituents. Core 15, however, is predominantly feldspar, volcanic glass, and rock fragments throughout its entire length.

c. Southeastern Ross Sea - Five of the seven cores taken by GLACIER in this area extend over a distance of more than 130 miles along the Ross Ice Shelf. In these, the top comparatively rich organic zone, varying from 5 to 7 inches thick, appears to indicate a period of relatively high plankton productivity. Below this, the microfauna are sparse but increase somewhat at the bottom of the two longest cores, 6 and 7. Volcanic glass and rock fragments are present in all of these cores, but their occurrences are so variable and irregular, due probably to glacial dumping, that they are useless for correlation. However, because of the high percentage of rock fragments in cores 4 and 5 and their contained pink feldspars, which are uncommon in the other cores, these sediments are probably derived from Roosevelt Island, immediately to the south under the Ross Ice Shelf.

Cores 1 and 2 taken by GLACIER somewhat farther north of the ice shelf are similar to those described. The calcium carbonate content of the silts from core 2 was analyzed. This decreases from a high of 3.75% at the top to a minimum of 2.0% at 9 to 12 inches depth and then increases to 2.75% at the bottom of the core. The data are not adequate for correlation, but indicate a low calcium carbonate content for Southern Ross Sea sediments.

d. Northwestern Ross Sea - The only other bottom sediments obtained in the Ross Sea were in the northwest sector in water depth exceeding 1,000 fathoms. EASTWIND sample 2, containing a high percentage of rock fragments and radiolarian tests, consists of surface mud taken from the bottom Nansen bottle of an oceanographic cast. Core No. 3 was taken

in an indentation in the Antarctic Continental Slope. Since its location is beneath the Ross Ice Pack on the side opposite the indentation from Cape McCormick, the nearest land about 140 miles west, the supply of coarse terrestrial sediment, except for occasional dumping from icebergs, should be relatively low. This dumping shows up in the 18- to 20-inch segment of the core where 61 percent of the sediment is sand size or coarser and 40 percent of this is composed of rock fragments. Except for this segment, the silt-size fraction is remarkably high and constant at approximately 50 percent of the sample. This is not typical of glacial marine sediments. The content of radiolaria is adequately high for this core to be classed as a radiolarian ooze, except for the higher percentage of sponge spicules. Because of its location, slumping from the shelf could account for all or part of the sediments sampled.

2. Thurston Peninsula Area

a. BURTON ISLAND and GLACIER obtained thirteen bottom sediment samples close inshore along the Thurston Peninsula for a distance of over 90 miles from 101°57'W to 96°50'W. The bathymetry along this coast is extremely irregular and the bottom sediments vary in texture and composition. Two submarine rifts with depths in excess of 500 fathoms were crossed along the coast. These are to the east and west of Noville Peninsula. It is impossible to tell their extent to the north from the available soundings, but oceanographic stations over them sampled warm Antarctic Circumpolar Water at depth, which indicates they must be open to the north.

In texture, sediments range from silty sands on the shoals to pebbly silty clays in the deeps. For the most part, they are gray to brown in color, of medium low to medium high sphericity, subangular in roundness, and dull-pitted to polished-pitted in surface texture. Feldspar is the predominant mineralogical constituent while rock fragments are secondary. Quartz, pyroxene, and mica also are important constituents. All grains are fresh and unweathered. Very few radiolarians and diatoms are evident in these sediments, but the Globigerina and benthic foraminifera content total as high as 55 percent, especially where the bottom water temperature was found to be warmer than 0°C. In the few cores that are long enough, and in which the biological content at the surface is prominent, it appears that no appreciable organics, except for sponge spicules, extend to a depth greater than 3 to 4 inches.

b. Three cores were obtained by the ships north of Thurston Peninsula but still on the shelf in depths of 300 fathoms or less. Two of these cores in 225 and 235 fathoms consist primarily of feldspar and rock fragments with relatively little biological constituents, except for appreciable amounts of fecal pellets in GLACIER core 14. In texture, these 2 cores average from silty mud to sandy mud, particularly in their surface layers. GLACIER core 13 in 300-fathoms depth, however, ranges from clayey silt to silty mud in texture and consists primarily of

feldspar and quartz except at its bottom. Here rock fragments predominate, and the texture is sandy mud. Also, this core contains 30 percent Globigerinoides at its top and traces of coral fragments, benthic foraminifera, sponge spicules, fecal pellets, and radiolaria in segments throughout its length.

c. One sediment sample was obtained from the bottom Nansen bottle of a BURTON ISLAND cast in 1,300 fathoms of water at the base of the Antarctic Continental Slope. Although this sample was collected at 70°48'S, it contained 80 percent Globigerinoides, 5 percent spicules, and only 15 percent inorganic constituents. Its contents may result from slump of material down the Continental Slope.

3. Peter I Island Area

a. North of the Bellingshausen Sea, 2 cores were obtained in the vicinity of Peter I Island. BURTON ISLAND sample 9, taken in 1,450 fathoms on the island's western slope, averaged 95 percent volcanic ash and 5 percent planktonic biological remains. GLACIER sample 15 was obtained in 2,025 fathoms about 90 miles east of Peter I Island. This core consists of silty clay throughout, but has some sandy constituents in the 2 to 5, 7.5 to 9.25, and 23 to 25 inch segments. Feldspar is the predominant mineral while volcanic glass, rock fragments, and quartz are secondary. Radiolarians are the most common biological constituent and reach a maximum of 30 percent at the top. In certain segments, fecal pellets are prominent.

4. Adelaide Island Area

a. Five bottom sediment samples were obtained from GLACIER in the vicinity of Adelaide Island. Three of these were at the north end off Matha Strait while the other two were 45 miles west of the south end. These two groups of cores are remarkedly different in texture, but are similar in the distribution of organic and inorganic constituents.

The cores off Matha Strait are composed of grayish olive gravel and pebbly sand to a depth of 6 inches. Only one core penetrates deeper than this, and it contains medium bluish gray clayey silt from here to the bottom with an increase in amount of the sand fraction at 6 to 8 inches and 16.5 to 18.5 inches. Feldspar in the predominant mineral constituent of this core while quartz and rock fragments are secondary. Volcanic glass averages 10 to 15 percent from the 3- through 14.5-inch segment, and a trace of pyrite is evident from 14.5 inches to the bottom. Traces of planktonic micro-organisms, sponge spicules, and fecal pellets exhibit an irregular distribution up to 10 percent throughout the core. However, these range from 20 to 25 percent of the sand size in the upper 8 inches.

b. Both southern cores consist of grayish olive silty clay or clayey silt of medium low to medium sphericity from their tops to a depth

of 13 inches. Below this, core 19 is composed of medium gray silty mud to pebbly silty sand of medium low sphericity, while core 20 is composed of dark greenish gray silty mud of medium low sphericity. Lithologically, both cores have feldspar as their predominant mineral to the 13-inch depth, but below this, rock fragments increase to equal quantity. Quartz is an important constituent throughout these cores. A trace of volcanic glass also is present in both, and pyrite appears as a trace from about the 15-inch depth to the bottom of the cores. Above 13 inches, the biological content is 25 percent or more and is sufficiently high in diatoms in the surface layers for these to be classified as diatomaceous oozes. Below 15 inches, the biological content is never more than 5 percent. The 13- to 15-inch layers of both cores appear to be a transitional zone.

c. Mineralogically and biologically the northern and southern Adelaide Island cores correlate reasonably well. The top 6 inches of the Matha Strait cores correspond to the top 13 inches of the southwestern cores, while the 6- to 8-inch zone of the one long northern core agrees with the 13- to 15-inch transition zones of the southern ones. In addition, the segments below the transition zones also appear comparable. Texturally, however, these two groups of cores are exactly the inverse of each other. The only place they agree is in their transition zones. This textural anomaly is probably dependent upon debris-carrying ice reaching these localities and partially melting.

5. Rock Samples

a. Rock samples were collected from various islands in the Antarctic. A sample of vesicular basalt was obtained from the top of Scott Island (67°24'S, 179°55'W). Samples of diorite were collected from Mulroy Island (71°54'S, 97°51'W) and a rock islet off Williams Island, Thurston Peninsula (71°54'S, 100°00'W). Visual identification of a rock sample from Brabant Island, Palmer Peninsula (64°25'S, 62°17'W), appeared to be quartz-diorite. Samples from Penguin Island, Palmer Peninsula (62°05'S, 57°52'W), were of volcanic origin. Lichens and mosses were collected from Scott Island, Mulroy Island, Thurston Peninsula, and Penguin Island.

VIII. MISCELLANEOUS OBSERVATIONS

A. Transparency and Water Color

Table 2 summarizes transparency and water color data obtained on DEEP FREEZE 60. Transparency estimates were obtained by averaging the depths in meters at which the white and black Secchi discs (about 30 cm. in diameter) disappeared from sight on lowering and reappeared on raising. Aside from the limitations attendent with such observations, it is felt that they have some gross relative value in describing sea water transparency. Several estimates of water color were made by visual comparison with a modified blue-green-yellow Forel scale. Determinations were made in percent yellow, but are listed in the table by actual color.

In the deeper portion of the Western Ross Sea, transparencies averaged 14 meters for the white disc and 7 for the black; water color ranged from blue to deep blue. In the shallower water of McMurdo Sound and Ross Ice Shelf, transparencies were considerably less, averaging about 7 meters for the white disc. These low values and prevalence of greenish blue water color are attributed to the summer plankton bloom.

Observations taken in Thurston Peninsula area during late February resulted in values for the white disc of 15 to 17 meters. Water color was described as deep blue.

B. Gravity Observations

A subsidiary program of gravity observations was conducted with a LaCoste and Romberg geodetic gravimeter. This instrument has a range of 6,000 mgals and a low drift rate. All possible check points and pendulum bases were occupied enroute to and from the Antarctic. A minimum of 4 reading was taken and averaged at each observation site. The values obtained, were referred to the Hydrographic Office datum and are presented in Table 3.

TABLE 3. GRAVITY OBSERVATIONS

Date of Observations: 25 Nov 1959 - 23 Feb 1960

Reference Station: Hydrographic Office - Rm. 144

Sta. No.	Latitude	Longitude	Elev. M	Observed Gravity	Remarks
1	38°50.8'N	76°55.7'W	90	980.0841	Hydro Rm. 144

APPENDIX A

OCEANOGRAPHIC STATION DATA

SHIP	HYDRO REFERENCE NO.
USS ATKA	00649
USS BURTON ISLAND	00650
USCGC EASTWIND	00651
USS GLACIER	00652

EXPLANATION OF OCEANOGRAPHIC STATION DATA

GENERAL

Each of the items appearing on the data pages is explained below. The vertical arrows shown in some of the column headings indicate the location of decimal points. The presence of asterisks to the left of data indicates these data are doubtful; hence, they were not used in the construction of the curve from which interpolated values (standard depth values) were derived. Observed values which were obviously invalid were omitted entirely.

SURFACE OBSERVATIONS

1. Cruise Number. This number is arbitrarily assigned. It identifies a cruise and provides a means of sorting from the IBM file all cards pertaining to that particular cruise. For operation DEEP FREEZE 60, Reference Number 00649 was assigned to USS ATKA; Reference Number 00650, USS BURTON ISLAND; Reference Number 00651, USCGC EASTWIND; and Reference Number 00652, USS GLACIER.

2. Station Number. Stations are numbered consecutively, starting with one, at the beginning of each cruise. Therefore, for a complete identification of a particular station, both cruise and station numbers are necessary.

3. Date. Month and day are given in Arabic numerals. The last three figures of the year are indicated. The hour is Greenwich Mean Time and is that hour nearest to the start of the first cast.

4. Latitude and Longitude. The position of the station is given in degrees and minutes.

5. Sonic Depth. Sonic Depth is the uncorrected sounding for the station, recorded in meters.

6. Maximum Sample Depth. The maximum depth from which a water sample was obtained at the station is given to the nearest 100 meters.

7. Wind. Wind speed is given in meters per second. Direction from which the wind blows is coded in degrees true to the nearest ten degrees. The last zero is omitted. North is 36 on this scale and calm is 0. See Table I, Compass Direction Conversion Table for Wind, Sea, and Swell Directions.

8. Anemometer Height. The height of the anemometer above the waterline is given in meters.

9. Barometric Pressure. Barometric pressure is coded in millibars, neglecting the 900 or 1000. Thus, 996 millibars is coded as 96 and 1008 millibars is coded on 08.

10. Air Temperature. Dry bulb and wet bulb temperatures are entered to the nearest tenth of a degree (centigrade). A negative temperature is coded by dropping the minus sign and adding 50; thus - 10° is coded as 60.

11. Humidity. The percent of humidity is coded directly, 100 percent being coded as 99.

12. Weather. Weather is coded as indicated in Table II, Numerical Weather Codes - Present Weather.

13. Cloud. Cloud type and amount are coded as indicated in Table III, Cloud Type, and IV, Cloud Amount.

14. Sea. Sea direction and amount are coded as indicated in Tables I and V, respectively.

15. Swell. Swell direction and amount are coded as indicated in Table I and VI, respectively.

16. Visibility. Visibility is coded as indicated in Table VII, Visibility.

SUBSURFACE OBSERVATIONS

1. Sample Depth. Observed (actual) depth of each sample is given in meters. Interpolated values at standard depths are also given. The standard depths, in meters are: 0, 10, 20, 30, 50, 100, 150, 200, 250, 300, 400, 500, 600, 800, 1000, 1200, 1500, 2500, 3000, and thence every 1000 meters.

2. Temperature. The centigrade temperature is given in degrees and hundredths.

3. Salinity. Salinity is given in parts per thousand (by weight) to two decimal places.

4. Sigma-t. To convert to density divide by 1000 and add 1. Thus, a sigma-t value of 22.35 converts to a density of 1.02235.

5. Delta-D. The values in the columns are the anomalies of dynamic depths from the surface to each level in dynamic meters. Each entry is the cumulative sum of the anomalies of dynamic depth of the layer above. These values have been computed for the standard depths only, and serve to identify computed points.

6. Dissolved Oxygen. These values when given are in milliliters per liter to two decimal places. Values of 10.00 or above rarely occur and are coded as 9.99.

7. Sound Velocity. Sound velocity is given in feet per second to one decimal place, corrected for pressure at each depth.

TABLE I. COMPASS DIRECTION CONVERSION TABLE FOR WIND, SEA, and SWELL DIRECTIONS

Code	Direction
00	Calm
01	5° to 14°
02	15° to 24° NNE
03	25° to 34°
04	35° to 44°

32	315° to 324° NW
33	325° to 334°
34	335° to 344° NNW
35	345° to 354°
36	355° to 4° N
99	Variable or unknown

TABLE II NUMERICAL WEATHER CODES—PRESENT WEATHER

00 Cloud development NOT observed or NOT observable during past hour.	01 Clouds generally dissolving or becoming less developed during past hour.	02 State of sky on the whole unchanged during past hour.	03 Clouds generally forming or developing during past hour.	04 Visibility reduced by smoke.	05 Haze.	06 Widespread dust in suspension in the air, NOT raised by wind, at time of observation.	07 Dust or sand raised by wind, at time of observation.	08 Well developed dust devil(s) within past hour.	09 Duststorm or sandstorm within sight of or at station during past hour.
10 Light fog.	11 Patches of shallow fog at station, NOT deeper than 6 feet on land.	12 More or less continuous shallow fog at station, NOT deeper than 6 feet on land.	13 Lightning visible, no thunder heard.	14 Precipitation within sight, but NOT reaching the ground.	15 Precipitation within sight, reaching the ground, but distant from station.	16 Precipitation within sight, reaching the ground, near to but NOT at station.	17 Thunder heard, but no precipitation at the station.	18 Squall(s) within sight during past hour.	19 Funnel cloud(s) within sight during past hour.
20 Drizzle (NOT freezing and NOT falling as showers) during past hour, but NOT at time of ob.	21 Rain (NOT freezing and NOT falling as showers) during past hour, but NOT at time of ob.	22 Snow (NOT falling as showers) during past hour, but NOT at time of observation	23 Rain and snow (NOT falling as showers) during past hour, but NOT at time of observation	24 Freezing drizzle or freezing rain (NOT falling as showers) during past hour, but NOT at time of observation.	25 Showers of rain during past hour, but NOT at time of observation.	26 Showers of snow, or of rain and snow, during past hour, but NOT at time of observation.	27 Showers of hail, or of hail and rain, during past hour, but NOT at time of observation.	28 Fog during past hour, but NOT at time of observation.	29 Thunderstorm (with or without precipitation) during past hour, but NOT at time of observation.
30 Slight or moderate duststorm or sandstorm has decreased during past hour.	31 Slight or moderate duststorm or sandstorm no appreciable change during past hour.	32 Slight or moderate duststorm or sandstorm has increased during past hour.	33 Severe duststorm or sandstorm, has decreased during past hour.	34 Severe duststorm or sandstorm, no appreciable change during past hour.	35 Severe duststorm or sandstorm, has increased during past hour.	36 Slight or moderate drifting snow, generally low.	37 Heavy drifting snow, generally low.	38 Slight or moderate drifting snow, generally high.	39 Heavy drifting snow, generally high.
40 Fog at distance at time of observation, but NOT at station during past hour.	41 Fog in patches.	42 Fog, sky discernible, has become thinner during past hour.	43 Fog, sky NOT discernible, has become thinner during past hour.	44 Fog, sky discernible, no appreciable change during past hour.	45 Fog, sky NOT discernible no appreciable change during past hour.	46 Fog, sky discernible, has begun or become thicker during past hour.	47 Fog, sky NOT discernible, has begun or become thicker during past hour.	48 Fog, depositing rime, sky discernible.	49 Fog, depositing rime, sky not discernible.
50 Intermittent drizzle (NOT freezing) slight at time of observation.	51 Continuous drizzle (NOT freezing) slight at time of observation.	52 Intermittent drizzle (NOT freezing) moderate at time of ob.	53 Continuous drizzle (NOT freezing), moderate at time of ob.	54 Intermittent drizzle (NOT freezing), thick at time of observation.	55 Continuous drizzle (NOT freezing), thick at time of observation.	56 Slight freezing drizzle.	57 Moderate or thick freezing drizzle.	58 Drizzle and rain, slight.	59 Drizzle and rain, moderate or heavy.
60 Intermittent rain (NOT freezing), slight at time of observation.	61 Continuous rain (NOT freezing), slight at time of observation.	62 Intermittent rain (NOT freezing), moderate at time of ob.	63 Continuous rain (NOT freezing), moderate at time of observation.	64 Intermittent rain (NOT freezing), heavy at time of observation.	65 Continuous rain (NOT freezing), heavy at time of observation.	66 Slight freezing rain.	67 Moderate or heavy freezing rain.	68 Rain or drizzle and snow, slight.	69 Rain or drizzle and snow, moderate or heavy.
70 Intermittent fall of snowflakes, slight at time of observation.	71 Continuous fall of snowflakes, slight at time of observation.	72 Intermittent fall of snowflakes, moderate at time of observation.	73 Continuous fall of snowflakes, moderate at time of observation.	74 Intermittent fall of snowflakes, heavy at time of observation.	75 Continuous fall of snowflakes, heavy at time of observation.	76 Ice needles (with or without fog).	77 Granular snow (with or without fog).	78 Isolated starlike snow crystals (with or without fog).	79 Ice pellets (sleet, U. S. definition).
80 Slight rain shower(s).	81 Moderate or heavy rain shower(s).	82 Violent rain shower(s).	83 Slight shower(s) of rain and snow mixed.	84 Moderate or heavy shower(s) of rain and snow mixed.	85 Slight snow shower(s).	86 Moderate or heavy snow shower(s).	87 Slight shower(s) of soft or small hail with or without rain or rain and snow mixed.	88 Moderate or heavy shower(s) of soft or small hail with or without rain or rain and snow mixed.	89 Slight shower(s) of hail, with or without rain or rain and snow mixed, not associated with thunder.
90 Moderate or heavy shower(s) of hail, with or without rain or rain and snow mixed, not associated with thunder.	91 Slight rain at time of ob., thunderstorm during past hour, but NOT at time of observation.	92 Moderate or heavy rain at time of ob.; thunderstorm during past hour, but NOT at time of observation.	93 Slight snow or rain and snow mixed or hail at time of observation.; thunderstorm during past hour, but not at time of observations.	94 Mod. or heavy snow, or rain and snow mixed or hail at time of ob.; thunderstorm during past hour, but NOT at time of observation.	95 Slight or mod. thunderstorm without hail, but with rain and/or snow at time of observation.	96 Slight or moderate thunderstorm, with hail at time of observation.	97 Heavy thunderstorm, without hail, but with rain and/or snow at time of observation.	98 Thunderstorm combined with duststorm or sandstorm at time of observation.	99 Heavy thunderstorm with hail at time of observation.

TABLE III. CLOUD TYPE

Code	
0	Stratus or Fractostratus
1	Cirrus
2	Cirrostratus
3	Cirrocumulus
4	Altocumulus
5	Altostratus
6	Stratoscumulus
7	Nimbostratus
8	Cumulus or Fractocumulus
9	Cumulonimbus

TABLE IV. CLOUD AMOUNT

Code	
0	No clouds
1	Less than 1/10 or 1/10
2	2/10 and 3/10
3	4/10
4	5/10
5	6/10
6	7/10 and 8/10
7	9/10 and 9/10 plus
8	10/10
9	Sky obscured

TABLE V. SEA AMOUNT

Code	Mean Max. Height of Sea Waves in feet (Approx.)	Description
0	0	Calm (glassy)
1	0 - 1/3	Calm (rippled)
2	1/3 - 1 2/3	Smooth (wavelets)
3	1 2/3 - 4	Slight
4	4 - 8	Moderate
5	8 - 13	Rough
6	13 - 20	Very rough
7	20 - 30	High
8	30 - 45	Very high
9	over 45	Phenomenal+

+ As might be expected in center of hurricane

TABLE VI. SWELL AMOUNT

Code	Approximate Height (feet)	Description		Approximate Length (feet)
0	------	No swell		------
1	1 to 6	Low swell	Short	0 to 600
2			Long	Above 600
3	6 to 12	Moderate	Short	0 to 300
4			Average	300 to 600
5			Long	Above 600
6	Greater than 12	High	Short	0 to 300
7			Average	300 to 600
8			Long	Above 600
9	------	Confused		-----

TABLE VII. VISIBILITY

Code		
0	Dense Fog	50 yards
1	Thick Fog	200 yards
2	Fog	400 yards
3	Moderate Fog	1000 yards
4	Thin Fog or Mist	1 mile
5	Visibility poor	2 miles
6	Visibility moderate	5 miles
7	Visibility good	10 miles
8	Visibility very good	30 miles
9	Visibility excellent	Over 30 miles

APPENDIX B

SEDIMENT ANALYSIS SUMMARY SHEETS

EXPLANATION OF SEDIMENT ANALYSIS SUMMARY SHEETS

Results of bottom sediment analysis performed by the U. S. Navy Hydrographic Office are recorded on the sediment analysis sheet. Almost all bottom samples are analyzed weeks after the collection of the samples; therefore, various procedures normally carried out during a routine sediment analysis are not attempted. Determinations such as: wet density, water content, porosity, etc., are not possible after the samples have lost their "in situ" moisture; therefore, these parameters are not included on the analysis sheet.

The following is a description of the terms employed on the sediment analysis sheets:

1. Ship. The name of the ship used for collecting bottom sample.

2. Sample Number. A consecutive number, commencing with 1, assigned to each bottom grab sample or core taken successively throughout the cruise.

3. Latitude. Expressed in degrees, minutes, and seconds.

4. Longitude. Expressed in degrees, minutes, and seconds.

5. Date. Day (GMT), month, and year.

6. Cruise. The code name of the operation during which the bottom sample was taken.

7. Sampler Type. Identified by name or designation of device employed.

8. Water Depth. The uncorrected sonic sounding recorded to the nearest whole fathom and meter.

9. Core Length. Recorded to a fraction of an inch and centimeter as observed in the laboratory. This information is not given when a grab sampler was employed.

10. Core Penetration. Recorded to a fraction of an inch and centimeter as observed in the field. This information is not given when a grab sampler was employed.

11. Laboratory Number. A reference number assigned to each subsample which is retained in the laboratory sample file.

12. Subsample Depth in Core. Depth from the core top of the subsample top and bottom recorded to a fraction of an inch. This information is not entered when a surface grab sample was obtained.

13. Sediment Type. Determined by the sand, silt, and clay ratios of the sample based on the F.P. Shephard sediment triangle with modification of coarser material taken from Willman.

14. Color. Based on the Geological Society of America Rock-Color Chart. For those samples where color was not determined in the field, the sample was moistened in the laboratory for a color determination.

15. Odor. A laboratory description. A qualitative description of any noticeable odors.

16. Size Analysis and Statistical Measures. Sample size fraction values are based on dry weight and given in phy (ϕ) units to the nearest whole percent. An American Instrument Company sieving machine and U.S. standard sieves were used for determining sand and larger fractions. The pipette method of analysis was used to determine silt, clay, and colloid fractions.

The following table is presented for the conversion of phi units to millimeters:

$$[-\phi = \log_2 \text{diameter (millimeters)}]$$

Phi (ϕ)	Millimeters	Geological Classification
<-2	>4	Pebble
-2 to -1	4.0 to 2.0	Granule
-1 to 4	2.0 to 0.625	Sand
4 to 9	0.0625 to 0.00195	Silt
9 to 12	0.00195 to 0.00024	Clay
>12	<0.00025	Colloid

$Q_{1\phi}$ - (first phi quartile). Is the size read from the distribution curve above which 25 percent of the diameters in the distribution are larger and below which 75 percent of the diameters are smaller and is expressed to the nearest hundredth of a phi unit.

$Q_{3\phi}$ - (third phi quartile). Is the size read from the distribution curve above which 75 percent of the diameters in the distribution are larger and below which 25 percent of the diameters are smaller and is expressed to the hundredth of a phi unit.

QD_ϕ - (phi quartile deviation). Is that statistical parameter which is a measure of one-half of the spread of the quartiles and is expressed in phi units to the nearest hundredth with the given value computed from the formula:

$$QD_\phi = \frac{Q_{3\phi} - Q_{1\phi}}{2}$$

Sk_ϕ - (phi quartile skewness). Is that statistical parameter which is a measure of half the sum of the first and third quartile values less the median and is expressed in phi units to the nearest hundredth with the given value computed from the formula:

$$Sk_\phi = \frac{Q_{1\phi} + Q_{3\phi}}{2} = Md_\phi$$

Md_ϕ - (phi median). Is the middlemost member of the distribution curve above which 50 percent of the diameters in the distribution are larger and below which 50 percent of the diameters are smaller and is expressed to the nearest hundredth of a phi unit.

17. Subsample Dry Weight. Dry weight to the nearest hundredth of a gram.

18. Sphericity (avg.). A measure of the approach of the grain to the form of a sphere, expressed as one of the following: high, medium high, medium, medium low, or low. Determination was accomplished with a miscroscope and was based on a comparison of the sand and larger size fractions with a chart based on Waddell's method.

19. Roundness (avg.). A function of the sharpness of the grain edges and recorded as one of the following: very angular, angular, subangular, subrounded, rounded, or well rounded. Determination and laboratory procedures were the same as for Sphericity.

20. Surface Texture (avg.). A description of the physical appearance of the grain based on the scheme propoed by Krumbein and Pettijohn. These descriptions are recorded as dull or polished and one of the following: smooth, striated, faceted, frosted, pitted, or etched.

21. Mineral Content. A rough estimate of the percentage of mineralogical constituents contained in the sand size and larger materials based on a microscopic examination of the sample.

22. Biological Content. A rough estimate of the percentage of biological constituents contained in the sand size and larger materials based on a microscopic examination of the sample.

23. Remarks. Codes for mineral trace constituents and major foraminifera types, and space for additional information pertaining to the bottom sample.

MINERAL TRACE CODE

C—CALCITE
G—GARNET
MA—MAGNETITE
M—MICA
O—OLIVINE
P—PYROXENE

This core was composed of the remains of one sponge and a small amount of sandy mud which was insufficient for analysis.

MINERAL TRACE CODE

C—CALCITE
G—GARNET
MA—MAGNETITE
M—MICA
O—OLIVINE
P—PYROXENE

Core contained several small pebbles in the top 2" and one large pebble 0.88" X 0.63" X 0.5", 9.30 gm. at 7". The large pebble was not included in the analysis.

Pebbles composed of all major rock types.

b. −2φ to −1φ (%)	2	SKφ +0.05			3	SKφ +0.35	SKφ
c. −1φ to 0φ (%)	5	Mdφ 5.65			4	Mdφ 5.75	Mdφ
d. 0φ to 1φ (%)	5	Q1φ 2.15			4	Q1φ 2.00	Q1φ
e. 1φ to 2φ (%)	5	Q3φ 9.25			5	Q3φ 10.20	Q3φ
f. 2φ to 3φ (%)	6				5		
g. 3φ to 4φ (%)	6				6		
h. 4φ to 6φ (%)	17				17		
i. 6φ to 9φ (%)	20				20		
j. 9φ to 12φ (%)	14				14		
k. >12φ (%)	13				13		
17. SUBSAMPLE DRY WEIGHT (gm.)	22.04				30.00		
18. SPHERICITY (avg.)	Medium Low				Medium Low		
19. ROUNDNESS (avg.)	Subangular				Subangular		
20. SURFACE TEXTURE (avg.)	Polished-Pitted				Polished-Pitted		
21. MINERAL CONTENT (%)							
a. DOMINANT Feldspar	35				35		
b. SECONDARY Quartz	30				30		
c. TERTIARY Rock Fragments	30				30		
d. OTHER Volcanic Glass	Trace				Trace		
e. OTHER Pyrite	Trace				Trace		
f. TRACE (see remarks)	MA, M, P, O 5				MA, M, P, O 5		
22. BIOLOGICAL CONTENT (%)							
a. FORAMINIFERA (see remarks)	C Trace				C Trace		
b. RADIOLARIA	Trace				Trace		
c. DIATOMS	Trace				Trace		
d. OTHER Spicules	Trace				Trace		
e. OTHER							

23. REMARKS:

MINERAL TRACE CODE

C—CALCITE
G—GARNET
MA—MAGNETITE
M—MICA
O—OLIVINE
P—PYROXENE

FORAMINIFERA CODE

G—GLOBIGERINA TYPE (PELAGIC)
A—ARENACEOUS | Benthonic
C—CALCAREOUS |

U. S. Navy Hydrographic Office
OPERATION DEEP FREEZE 60, 1959 - 1960. OCEANOGRAPHIC SURVEY RESULTS, June 1961. 231 p., including 24 figs. (TR-82).

Contains a summary and results of oceanographic operations in the Antarctic and adjacent waters. Data on thermal structure, salinity, density, dissolved oxygen content, bottom sediments, and gravity are presented for the Ross and Amundsen-Bellingshausen Seas, McMurdo Sound, Bransfield Strait, Drake Passage, and in the area of the Antarctic Convergence. Distribution and concentration of sea ice is reported for these areas when present. A discussion of the Antarctic Convergence also is included.

Appendix A contains a tabulation of oceanographic data for 123 stations and Appendix B, the analysis of 48 bottom sediment samples.

1. Antarctic - oceanography
2. Antarctic - bottom sediments
3. Antarctic - ice
4. USS ATKA
5. USS BURTON ISLAND
6. USCGC EASTWIND
7. USS GLACIER
